The ingenious hypothesis that a given case of insanity may be due to infection and that hypernutrition might promote a cure by facilitating the formation of antibodies, or any other theory that may be set up to account for its favorable effect on the course of the disease, does not call for discussion here. The assumption is simply made that in a large proportion of patients suffering from various forms of the acute psychoses, promotion of the nutrition is a prominent indication of treatment. It is further assumed that the nature of the patient's malady is such as to impair more or less his cooperation with efforts made in his behalf, or even to induce him to offer the most determined resistance to them. Under the conditions postulated the effective application of any and all measures demands that the patient be all the time surrounded with adequate provisions for his control, or indeed be subjected to the exercise of arbitrary authority resting on a basis of physical force, either active or potential. For various reasons largely economic, because a physician experienced in such cases, the only proper source of arbitrary authority, should be always at hand to relax, or reinforce this, according to circumstances, these patients are best treated in a specially equipped institution.

THE STOMACH PAD

The procedure to which I wish first to call attention is the use of the stomach pad. My practical acquaintance with it was gained many years ago from a masseuse who conducted a very successful rest cure, and who regarded the employment of this measure as one of the principal factors which had contributed to the establishment of her reputation. Patients who had become emaciated to the last degree, through inability to digest their food, though they had been quite refractory to the most skilful medication, lavage and what not, promptly responded to the so-called rest cure, of which the stomach pad constituted one of the essential components, when all medicine, with the exception of indicated laxatives, was withdrawn. To be sure, these patients differed in many particulars from those under consideration. Their cooperation could be relied on. The full effects of rest in bed, thorough mastication and massage were available. Nevertheless, since the therapeutic problem is identical in each instance, if the stomach pad has any considerable utility in promoting digestion and assimilation, its claims should certainly command respectful attention.

The elaborate and convincing investigations of Henry Head[1] demonstrate that the functional activity of the several abdominal and thoracic organs or viscera is sensibly promoted by stimulation of the skin lying over them. There are pathways for the passage of nervous stimuli from the skin through the spinal cord and thence to the underlying viscus; hence it would appear that the empiric, and for centuries at least popular practice of counterirritation, after all, rests on a sound scientific basis.

The heat is conveniently applied by means of dry wheat bran, as follows: A cotton or linen container of the proper size and shape is filled with bran. I advise having it extend the whole width of the abdomen from the nipples to the pubes, and made with a box border about 2½ inches in depth. The pad should not be stuffed so full that it cannot easily conform to the contour of the body. It may be heated in an oven at a temperature of about 300 F. to be made ready for application. When applied, it may be covered with oiled silk and blankets to retain the heat. This is much lighter, and patients usually pronounce it more comfortable than the various forms of moist or wet heat as, for instance, the flaxseed poultice. Though I was originally strongly prejudiced in its favor, the electric pad as a means of applying heat has for several reasons quite disappointed my expectations.

Incidentally it may be stated in this connection, although hardly a matter of minor importance, that the tranquilizing effect of the hot stomach pad, in cases characterized by considerable excitement, is sometimes quite striking. It was long ago demonstrated that in natural sleep the volume of blood in the extremities is sensibly increased and that consequently the brain becomes correspondingly anemic; hence for the purpose of dilating the vessels of the extremities and the portal circulation and thus facilitating sedation and hypnosis, the application of heat to the extremities and the epigastrium is a rational procedure. And, while in a large majority of highly excited cases when not used in conjunction with medicinal remedies it cannot be relied on to induce promptly either sleep or sufficient sedation, it embraces a principle of very wide application and enormous value in the treatment both of the psychoses and the neuroses, or combinations of them. The maximum sedative and hypnotic effect of the principle is of course attained by employment of the full hot bath, in conjunction with cold to the head.

FEEDING

When the food is well relished, the solids and semisolids thoroughly masticated, and liquids slowly sipped, no doubt the process of digestion progresses much more easily and satisfactorily than when opposite conditions prevail. Unfortunately, in the psychoses it only too frequently happens that none of these aids to digestion are available; even in those cases in which by persuasion, scolding, coaxing, or what not, enough food may be swallowed, all of them are commonly wanting. In these patients the use of the stomach pad is of distinct value. If it can be kept in position while the meal is being given, the patient meanwhile lying on his back, as is the ordinary practice when mental disorder does not have to be reckoned with, so much the better; the application is continued from forty-five minutes to an hour after the meal is finished.

When liquid food must be introduced artificially, let this, at or slightly above normal bodily temperature, pass into the stomach very slowly through a small tube, the pad being employed as indicated above. To be sure, since there are numerous and wide variations in the phenomena presented by individual cases of the psychoses in which "building up" measures are urgently demanded, as well as in others, no fewer or less pronounced modifications have to be made in the practical application of any procedures intended for their relief. Long and intimate experience with these phenomena and their individual variations is essential to a reasonable comprehension of their significance; hence such experience is likewise essential to the exercise of sound judgment in the employment of any and all means that may be advocated or made use of in the treatment of the psychoses.

REST IN BED

In a very considerable proportion of patients afflicted with various forms of the acute psychoses, whose symptoms are such as to present formidable obstacles to the problem of satisfactorily meeting the nutritional indications, intense and inveterate restlessness is one of the most common and prominent morbid manifestations. Even when a liberal amount of nutritious food is introduced and well digested, the patient may steadily lose weight on account of the exhaustive character of his restlessness or agitation together with the concomitant loss of sleep; hence an effort to secure even a modicum of rest should never be neglected. It almost never happens that rest in bed, as it is carried out in the so-called rest cure, is feasible; even in the most favorable cases, modifications or compromises have to be made. And since patients will rarely accept massage in lieu of exercise, even in those rare instances in which absolute rest might be secured, it would be of doubtful advantage.

---

[1] Head, Henry: Brain, 1893, iv, 6.

Unhappily, in practice we are usually obliged to content ourselves with making the attempt, in each case, to strike a balance between the damage the patient is sustaining from the excitement incident to the natural course of his disease, and the injury he might suffer from employment of some of the various resources at our command for the purpose of reducing the morbid activity. As an exceedingly general proposition, if in the course of a few days by dint of intelligent and persevering effort a patient can be successfully trained to remain in bed till noon without persisting in exhaustive efforts of resistance, a position of enormous advantage has surely been gained in the nutritional struggle. After dinner the desired amount of outdoor air and exercise may be prescribed.

FRESH AIR AND SOUNDPROOFED ROOMS

The value of an abundance of fresh air as an essential element in the promotion of nutrition can hardly be overestimated; and unfortunately it only too frequently happens that, from various considerations, the class of patients under discussion cannot be much if at all outdoors for weeks or months together; and, indeed, at the same time it may be expedient to keep the doors and windows of their rooms closed. Since it has been demonstrated over and over again that continued close confinement in poorly ventilated rooms is by far the most potent etiologic factor of pulmonary tuberculosis, that this cause operates by reducing the nutrition, and that the nutrition is most effectively restored and the disease cured by keeping the patient continuously in the open air, the vast importance of sound-proof or muffled rooms with ample forced ventilation in attaining the end in view is obvious. Observed from a still different angle, the enormous advantage of these rooms in the solution of the difficult nutritional problem which many cases of the acute psychoses present is plainly seen. The more or less profound disorder of digestion inevitably produced by the regular administration of full doses of sedatives and hypnotics is too well understood to require comment. In the practical operation of a hospital, however, it is manifestly unjust to permit the disturbance made by, say, 5 per cent. of the patients to deprive the remaining 95 per cent. of perhaps several hours' sleep at night and seriously interfere with their comfort and tranquillity by day as well. Without the resource which these rooms supply when instances of individual excitement occur, the principle of "the greatest good to the greatest number" has to be brought into requisition. When these rooms are available, however, the physician is relieved of all obligation to administer a harmful remedy to one of his patients for the benefit of others. And though the degree of sound proofing falls far short of what might be desired, ten years of experience with these rooms has confirmed the conviction which prompted their installation; this conviction is that they are indispensable to the fair and proper treatment of a considerable proportion of cases of the acute psychoses. Unfortunately, candor compels me to confess that the conclusions I have reached in this connection and the facts on which I have based them are all ignored, almost entirely, both by our profession and the laity. It may be asserted without much fear of contradiction that no instance can be cited in which either a patient's family or his physician in selecting accommodations for treatment ever gave the slightest weight, in reaching a decision, to the considerations here advocated. The installation and operation of these rooms involves a considerable expense, and in the existing attitude of the public and our profession regarding their value, whoever makes use of them may indeed augment his own sense of satisfaction and self respect, but from a financial standpoint he places himself in a position to be called a fool for his pains.

As a means of improving the nutrition, it is altogether feasible to keep a considerable proportion of patients suffering with various forms of the acute psychoses outdoors during the day time, using the same methods to protect them against inclemencies of weather as are followed in tuberculous cases. For various reasons, however, as a reliable measure of treatment in these cases, it would rarely if ever be expedient to attempt to inaugurate outdoor sleeping. For the satisfactory application of the outdoor method of treatment, enough pavilions are desirable to permit of proper classification. These should open to the south and be provided with concrete floors and walks leading to them so that weather conditions do not have to be reckoned with. The salutary effects of outdoor life in promoting nutrition do not demand the services of an advocate.

HYDROTHERAPY, MASSAGE AND OCCUPATION

Although hydrotherapy, massage and occupation may be regarded as somewhat less direct in aiding the nutritional process than some of the agencies previously mentioned, when conditions are favorable to or perhaps even admit of their exhibition, any or all of them may be of great service. The indications for their use, and the form and manner of their application, especially with reference to the last, could be easily expanded to the dimensions of a chapter. In conclusion and somewhat by way of digression, and at the same time as a note of caution, permit me to state briefly a concrete case, illustrating the unfortunate effects that may result *from insufficient supervision of* prescribed occupation.

Some years ago while in state service, I prescribed a review of her school work for a young woman formerly a teacher. This patient of the dementia praecox type had been comparatively comfortable for several years, with some supervision dressed herself properly, was able to participate in the various forms of diversion usually provided in state hospitals, and was in a fairly satisfactory state of bodily health. She took to the work eagerly; but while her teacher and myself were congratulating ourselves on the success of our plan, the patient passed quite rapidly into an attack of high excitement very much like that which occurred at the onset of her disease, and from which she emerged a few months later on a little lower plane than before. Whenever this circumstance has recurred to my mind, it has always been accompanied by the conviction that this defenseless patient was a victim of my misdirected enthusiasm and inadequate attention. Of course an experience of this kind does not cast discredit on occupation as a valuable resource in the care and treatment of the insane; it simply emphasizes the necessity of studying each and every case both deeply and broadly, and of maintaining a close observation of and active interest in them to the end of the chapter.

A RAPID AND SIMPLE METHOD OF TESTING DONORS FOR TRANSFUSION [*]

PEYTON ROUS, M.D.
AND
J. R. TURNER, M.D.
NEW YORK

The increasing popularity of transfusion as a therapeutic measure has brought with it the need of a test whereby the suitability of donors may be rapidly determined. There are already many instances on record of serious symptoms or death following the rapid breaking down of blood after transfusion. The evidence is convincing that such instances may be avoided if a donor is selected beforehand by means of certain simple tests carried out in vitro. Unfortunately these, as performed at present, require time and labor. It is with the aim of providing a test rapid and simple enough to be employed even in emergencies that the following method has been devised:

METHOD

Collection of the Blood.—The blood is taken from the patient and the prospective donors in a 1:10 mixing pipet, such as is used in counting leukocytes. The pipet is rinsed beforehand with 10 per cent. sodium citrate in water; the citrate solution is drawn up to the mark 1; the pipet is rapidly filled with blood from a puncture of the ear or finger; and without pause the mixture is expelled into a small, narrow test tube. There is thus obtained a citrated blood containing slightly less than 1 per cent. of citrate. The pipets which we have employed hold only 0.25 c.c. of fluid. This much blood is easily obtained from a single puncture. There is no objection to increasing the flow by pressure. Should it cease before the pipet is full, the blood must be at once expelled into a test tube, in order that it may mix with the citrate and clotting be avoided. The mixture is then taken up again, a new puncture made, and the pipet completely filled. After each blood is obtained, the pipet is rinsed with citrate, then with distilled water, then with fresh citrate, and it is ready for another blood. If several donors are to be tested, two pipetfuls of citrated blood should be obtained from the patient. It is best to take them from different puncture wounds, in order to avoid a possible clotting in the pipet.

Mixing.—The mixing is done in pipets with a capillary end—the so-called Wright pipets obtained by drawing out glass tubing in the flame. The citrated bloods are used as such, and two combinations are made of the patient's blood with that of each prospective donor—a mixture containing nine parts of the patient's blood to one of the donor's, and a mixture of equal parts of the two. The proportions used need be only approximate. In case of emergency the first of the mixtures will suffice, since by its use the most dangerous possibility, namely, that the blood of the recipient may destroy that of the donor, can be ruled out. Following the technic usual with Wright pipets, the capillary tube is marked, blood is drawn to the mark, and each column of the blood is separated with an air bubble from the next that is drawn up. To insure proper mingling, each mixture should be expelled on a slide, or Widal plate, and then drawn high in the pipet, which may be sealed off in the flame in case the examination is not to be made for some time.

Incubation.—No incubation in the ordinary sense is necessary. The pipets are kept at room temperature, and readings are begun after two minutes, if there is need to hurry. The readings are for agglutination, and even within two minutes this is plainly evident, except when the agglutinating forces are notably weak. In the final choice of a donor it is safest to rely on results obtained after the mixtures have stood for fifteen minutes. But the ruling out of individuals with unfit blood may be begun practically at once.

Readings.—The capillary end of each pipet is broken, a small drop of the blood expressed on a slide, a large drop of normal salt solution superimposed without mixing, a coverslip put on, and the preparation examined for agglutination under the microscope. Fresh preparations can be made at intervals if desired. The salt solution is not absolutely necessary; but very clear pictures are obtained as the blood spreads in it. When agglutination has occurred, the red cells show a characteristic clumping, sometimes in small masses, often in large ones that are very evident macroscopically. The clumps in each preparation are fairly uniform in size. The picture is absolutely different from that in mixtures of nonagglutinating bloods under similar conditions. In these, the cells lie free or in rouleaux, just as in a single blood. But in agglutinating mixtures the cells are stuck together "every which way," and, where the film is thin, they do not separate but lie connected with one another in irregular heaps. If pressure is put on the coverslip, a very characteristic phenomenon may sometimes be seen. The agglutinated cells pull out in strands as though they consisted of some sticky substance. The most striking pictures are encountered when there are nine parts of an agglutinating blood to one that is agglutinated. Here large discrete masses lie scattered amid unclumped red cells.

If there is no clumping in the preparations made after the mixtures have stood fifteen minutes, the assumption is warranted that the bloods do not agglutinate or hemolyze each other. The experience of previous workers has taught that in such instances transfusion is safe. But if clumping is present in the 9:1 mixture and to a less degree or not at all in the 1:1 mixture, it is certain that the blood of the patient agglutinates that of the donor and may perhaps hemolyze it. Transfusion in such cases is dangerous. Clumping in the 1:1 mixture with little or none in the 9:1 indicates that the plasma of the prospective donor agglutinates the cells of the prospective recipient. The risk from transfusing is much less under such circumstances, but it may be doubted whether the blood is as useful as one which does not and is not agglutinated. A blood of the latter kind should always be chosen if possible.

For practical purposes these findings suffice. But if there is a desire to know whether *both* bloods contain agglutinins, a *1:9 mixture should be made. If this and the 9:1 mixture* show large clumps, whereas the clumps are smaller when the bloods are mixed in equal parts, two agglutinins must be present.[1] Should there be only one agglutinin, little clumping or none will be observed when the blood containing the agglutinin is diluted with nine parts of the other blood.

Difficulties.—The single technical difficulty of the method is that of clotting, and to avoid it the blood should be taken as rapidly as possible. With normal blood, trouble is seldom experienced, but in pathologic instances a thin web may form in the test tube into which the blood is expelled. The clotting begins in the calibrated tube of the pipet which, as the blood is taken, is swept free of citrate; and the use of a strong citrate (15 per cent.) will not prevent it. But the clot is always thin and may be picked out of the blood and the latter used for the tests. In the pipet even small clots are troublesome, since they form a locus for new ones when another blood is taken. They are best dissolved out with 5 per cent. potassium hydroxid.

---

[*] From the Laboratories of the *Rockefeller Institute for Medical Research.*

[1] This phenomenon has been described by Ottenberg in an interesting study of the conditions under which human bloods show agglutination. He used mixtures of defibrinated whole blood. (Ottenberg, R.: Jour. Exper. Med., 1911, xiii, 425.)

The likelihood that something else may be mistaken for agglutination is practically nil. The presence of fibrin strands and clumps of platelets and white cells absolutely differentiates bits of clot. Dried blood will not be found except in case of carelessness, and it is unlikely to cause confusion. Its nearly homogeneous, cheesy appearance under the microscope is sufficiently distinctive.

COMMENT

The test here described has some features in common with two of the methods already in use. Therefore, to point out wherein it is an advance over these will not seem amiss. Epstein and Ottenberg[2] use Wright's pipets, collecting blood in them for serum, and making the ultimate test mixtures in them. But the mixtures consist of serum and washed red cells; they are incubated for two hours, and the readings are macroscopic. Weil[3] employs citrated bloods, making, in test tubes, three mixtures of the same relative proportions as ours. Two c.c. of each blood are required, thus making necessary aspiration from a vein; the tubes are incubated for an hour, and the readings are macroscopic. By means of the test of Epstein and Ottenberg, aspiration from a vein is avoided; and by Weil's method the need to separate serum, wash the red cells and make reciprocal observations is done away with. In both instances, however, the time and the labor of testing donors is very considerable. Using our method, it is only necessary to obtain citrated bloods from a finger-prick, make two mixtures of them in capillary pipets, and, by reading with the microscope, the test is finished within a few minutes.

The method involves several important assumptions. They may be summed up in two questions: 1. Is the presence or absence of agglutination an index to the injurious qualities of a blood? 2. Are the microscopic findings with mingled, citrated bloods that have stood fifteen minutes at room temperature as certain in their indication as macroscopic findings after longer periods with mixtures of serum and 5 per cent. washed red cells—that is to say, as certain as the test most used at present?

The first question can be answered from the literature. Leaving from consideration disease in the donor, two injurious influences must be thought of when a foreign blood is introduced into the human body, namely, hemagglutination and hemolysis. The latter is far the more serious. Moss[4] has found in extensive observations that agglutination frequently occurs without hemolysis, but that hemolysis is always associated with or preceded by agglutination. This conclusion he has substantiated with seventy-five successful transfusions[5] in which the donors were selected by means of the agglutination test. It is well known that human beings fall into four groups as regards the agglutinins in their serum and the capacity of their corpuscles to be agglutinated. Moss was careful to select for transfusion individuals of the same group. Without going deeply into the matter we may say that, when serum and washed cells are used, reciprocal observations are necessary to determine whether two individuals belong to the same group. But in mixtures of whole citrated bloods, agglutination is only absent when this is the case.

In our test, agglutination is looked for with the microscope. This does not mean that macroscopic readings are impossible, for when clumping is at all outspoken in the slide preparation, it is plainly evident to the naked eye. Observations can, in emergency, be made in this way. But with the microscope, as one would naturally suppose, the readings are more sensitive and more precise. When antirabbit goat serum is mixed with rabbit red cells, clumping is observable microscopically in dilutions of serum much higher than those in which it is evident macroscopically in the test tube. This can be noted also with dilutions of an agglutinating human serum mixed with human red cells and with undiluted human serums weak in agglutinins. An agglutinative clumping is rarely doubtful microscopically, for the cohesion of the cells, even when only two or three are concerned in each clump, is absolutely different from rouleaux formation. In the test tube an agglutination is often difficult to distinguish from sedimentation; and the shaking which throws up the clumps into the fluid that they can be viewed may break them so that they do not reform.

Our experience is that if agglutination occurs at all it will be noticeable microscopically within five minutes. But it is better to let the mixtures stand longer. We have no hesitation in saying that agglutination can be told with the microscope as certainly after fifteen minutes as in two hours with the old macroscopic method. The explanation of this is probably simple. The clumps which become visible in the test tube after an hour or more are in general not the primary clumps of an agglutination, but the result of the massing together of many such clumps, which themselves are often small. Such secondary massing requires time, whereas the primary clumps form almost immediately.

That agglutination is sometimes better at room than at body temperature is well known.[6] Repeated trial has shown that the incubation of our agglutinating mixtures seldom increases the rapidity of the reaction. In some instances agglutination was much more pronounced after fifteen minutes at room temperature than in two hours at body heat. An altered distribution of the agglutinin may account for this.

It has been repeatedly shown that an excess of red cells may mask the presence of an agglutinin or hemolysin, and that hemolysis is much influenced by the presence of neutral serum. Agglutination is practically independent of this latter factor.[7] The influence of small amounts of sodium citrate does not seem to have been determined. The following is one of several experiments dealing with these points in their relationship to our test:

PROTOCOL OF EXPERIMENT

By venous puncture some cubic centimeters of a human blood, *A*, were taken with citrate (1 part 10 per cent. citrate to 10 parts blood) and some obtained for serum. Graded dilutions of the serum were made with salt solution, and mixed in small test tubes, as also in Wright's pipets, with equal parts of 5 per cent. suspensions in salt solution of certain washed red cells, *B* and *C*, which the undiluted serum agglutinated.

[6] Paltauf, R., in Kolle-Wassermann's Handbuch der pathogenen Mikroorganismen, ii.

[7] Hektoen, Moss, Ottenberg.

Dilutions of the plasma of the citrated blood *A* were made, similar to those of the serum, but the proportion of red cells was kept the same as in the original citrated blood. For this the citrated blood was distributed in a number of graduated tubes, centrifugalized rapidly, the supernatant fluid measured and diluted appropriately, and, when the red cells had been suspended and centrifugalized, all of the fluid was pipetted away except the original volume, and the cells were resuspended. The diluent used was sodium citrate in salt solution (1 part 10 per cent. sodium citrate to 9 parts 0.95 sodium chlorid). Nine parts of each of the combinations thus obtained were mixed in Wright pipets with one part of the whole citrated bloods *B* and *C*. The microscopic findings after fifteen minutes were compared with those in the serum mixtures after one and two hours. They gave identical results. Agglutination occurred when dilutions of serum or plasma up to 1 part to 7 of the diluent had been used for the mixtures, but not when 1 part to 15 had been employed. It was slight with 1:7 plasma and no better marked with 1:7 serum.

The experiment shows that a weak agglutinin may be demonstrated quite as well with mixtures of citrated whole bloods as with serum and a diluted suspension of washed red cells in salt solution. The interference of neutral red cells does not constitute a difficulty.

CONCLUSION

The test here described compares well in delicacy with those already in use, but we wish to insist only on its practicability. It enables one to determine within a few minutes, so far as agglutination and hemolysis are concerned, whether or not the blood of a donor is suitable for transfusion.

INTRASPINAL ADMINISTRATION OF ANTITOXIN IN TETANUS

NOTES ON A SERIES OF CASES *

MATTHIAS NICOLL, JR., M.D.
NEW YORK

As the result of a series of animal experiments conducted at the Research Laboratory of the Department of Health by Dr. William H. Park and myself[1] in order to determine the curative value of the intraspinal administration of tetanus antitoxin, and by which the superiority of this method was conclusively shown, every effort has been made during the past year to get into immediate touch with physicians and hospitals in and about the city of New York having cases of tetanus under their care, and induce them to give antitoxin as soon as possible by the following method:

1. From 3,000 to 5,000 units into the lumbar region of the spinal canal, preferably under an anesthetic, the volume of fluid injected being brought up to 10 or 15 c.c. by the addition of sterile normal saline, the exact amount being regulated according to the age of the patient and the amount of spinal fluid withdrawn.
2. Ten thousand units intravenously at the same time.
3. Repetition of the intraspinal dose in twenty-four hours.
4. A subcutaneous dose of 10,000 units three or four days later.

The well-recognized adjuvants to specific treatment — quiet, subdued light, sedatives, etc. — were, of course, understood as a necessary part of the therapeutic measures.

In no case has the physician objected to giving an intraspinal injection of antitoxin when so advised. Some, however, have given it in much greater quantities and by other methods in addition to that recommended, usually before I was able to consult with them.

Reports of twenty cases have thus been collected, in all probability representing a majority recognized as tetanus during this period in and about the city of New York. I have seen about half of the patients personally, in consultation. In others, the physicians have been kept in constant touch by telephone or through a clinical assistant during the progress of the case. In four cases, the histories have been furnished by the physician on request, the treatment given being exactly that recommended by the published article referred to above. In all cases the antitoxin used was furnished by the Department of Health.

A brief abstract of the clinical histories follows:

CASE 1.—F. D., girl, aged 10 years, seen in consultation with Drs. W. B. Anderton and A. A. Smith, fell, striking her forehead on the ground, receiving a lacerated wound three-quarters inch long over one brow. This was properly disinfected and sutured, healing promptly. Seven days later there was a facial paralysis on the side on which the wound was received. Thirty-six hours later, the jaws were firmly locked. Eight hours after this symptom was noted, the patient received 3,000 units of antitoxin intraspinally and 10,000 intravenously. Several subcutaneous injections were later given. The tetanic spasms were largely confined to the muscles of the jaw and pharynx, and later, the abdominal muscles; attempts at swallowing and the slightest external irritation caused contractions of the muscles of the throat and larynx, cyanosis, general convulsions and unconsciousness. Such convulsions occurred on fifty or more occasions, together with innumerable minor spasms. Pneumonia developed later, resolution being very long delayed. After a protracted convalescence and extreme emaciation, the patient made a perfect recovery.

CASE 2.—Thomas B., laborer, was admitted April 1, 1914, to the New York Hospital, with multiple lacerations of scalp and traumatic amputation of toes of the right foot. The wounds were immediately disinfected with iodin and irrigated with iodin solution. The following day, amputation of the toes was performed. April 10 (incubation nine days), there was slight stiffness of the jaws, which was not reported until the following morning. April 11, 1,500 units of antitoxin were given in the tissues about the wound and 3,500 intravenously, later on the same day, 3,000 units into the tissues about the wound and the same amount intravenously. April 12, the patient was very much worse, and was given 13,000 units intravenously, 8,000 intraneurally and 7,000 into the tissues about the wound. April 13, I was first consulted and the patient visited. His condition was still more unfavorable. There was marked opisthotonos. Eight thousand units of antitoxin were given into the spinal canal and 9,000 intravenously. Following the intraspinal injection the temperature rose to 105; there were severe headache, convulsions and semicoma. April 14, the patient was comatose throughout the day. April 15, the patient was conscious, and there was less rigidity. April 16, there was much less rigidity; the patient swallowed fairly well for the first time. The patient continued to improve and was discharged cured, April 30.

[1] Park, W. H., and Nicoll, Matthias, Jr.: Experiments on the Curative Value of the Intraspinal Administration of Tetanus Antitoxin, THE JOURNAL A. M. A., July 18, 1914, p. 235.

Comment.—Through a series of misunderstandings, this patient received still further intravenous injections of antitoxin following the intraspinal dosage, although an examination of his blood showed a tremendous antitoxic content. How much credit should be given the single intraspinal dose for the recovery in this case it is difficult to say. It is to be noted, however, that the first real improvement followed shortly after its administration.

Case 3.—Gustav H., aged 23, carpenter, admitted to St. Vincent's Hospital, June 27, 1914, had injured the tips of his fingers in some way, June 16. A definite history could not be obtained. Three days before this, the patient had a pustule on his neck, which was opened on the 20th. There was no other history of injury. June 21 (incubation five or eight days), he first noticed that his jaw was stiff; two days later, this was much more marked and had spread to the neck, back, arms and legs. On admission, there was marked opisthotonos, and the jaws were tightly locked. The slightest disturbance caused a convulsion. The patient's body rested on the heels and back of the head. The abdomen was boardlike. Treatment on the first day after admission consisted of 5,000 units of antitoxin intraspinally and 5,000 intravenously; June 28, 5,000 subcutaneously. The opisthotonos continued. July 1, 5,000 units were administered intraspinally, five hours after which the patient became delirious with a rise in temperature to 105. From July 4 to July 8, the rigidity decreased daily. July 18, the patient was discharged, cured.

Case 4.—Boy, said to have been vaccinated sixteen days previously, the vaccination wound having apparently become infected one week after vaccination, developed a slight stiffness of the jaw. Four days after the onset of this stiffness, he was admitted to the Roosevelt Hospital, where it was noted that the legs were very stiff, the arms less markedly so. There was slight trismus. He was given, on admission, 2,500 units intraspinally, 5,000 units intravenously and 1,500 units intramuscularly and in the tissues about the wound. The latter two injections were repeated the next day. On the third and fifth day he received intraspinal injections. Improvement in symptoms began about the third day and continued until discharge thirteen days after admission, when patient was well.

Comment.—This case, though comparatively mild, was unquestionably one of tetanus. Many of the injections given could well have been dispensed with.

Case 5.—G. T., boy, aged 10 years, was admitted to New York Hospital, Oct. 9, 1914. October 2, he ran a rusty nail into the sole of the left foot. October 9 (incubation seven days), there was stiffness of jaws, and some antitoxin (dose not known) was given intramuscularly. On admission, the teeth could not be separated and there was some tension in the calf of the left leg. All reflexes increased. Eight hours after admission, 3,000 units of tetanus antitoxin were given intraspinally and 1,500 about the wound, which had been opened. A few hours later, 1,000 were given intravenously. During the night, there were minor convulsions, accompanied by piercing screams every fifteen minutes. On the 12th, there were some dysphasia, abdominal rigidity and stiffness of the neck. The teeth were separated one-half inch. Intravenous injection of 9,000 units was made; there were general convulsions. October 11, there were convulsions lasting ten minutes, opisthotonos and a great deal of pain. October 12, there were convulsions for twelve minutes, stertorous breathing, cyanosis and great rigidity for half an hour following. October 13, the boy was comfortable and swallowed well. Intraspinal injection was made of 5,000 units. From October 14, there was a gradual improvement. The patient was discharged, cured, October 24.

Case 6.—M. B., boy, aged 8 years; was admitted to Bellevue Hospital June 17, 1914. The history of injury due to a fall six days previously and the presence of an old ulcer on the right shin did not serve to establish the incubation of the disease. Five days before admission his jaw began to be stiff. This stiffness extended to other muscles day by day. On admission he was absolutely rigid from his neck to his feet. His teeth could be separated but one-fourth inch. June 18, under an anesthetic, he was given 5,000 units of antitoxin intraspinally and 5,000 subcutaneously. The mind was perfectly clear; the arms alone could be moved freely. There were incontinence of urine and feces. The boy was fed by gavage. June 25, he was very much improved. He bent at the waist when lifted. The mouth opened five-eighths inch. June 28, he moved the legs and arms freely; the spine was no longer stiff; the mouth opened widely; he ate well.

Comment.—This child was in a desperate condition at the time of giving antitoxin. On theoretical grounds we should not expect that antitoxin would be of much avail, when given at so late a period of the disease, and yet the improvement followed so soon after its administration that it would seem that antitoxin should be given the credit for it.

Case 7.—R. M., boy, was admitted to the Hospital of the Holy Family, April 15, 1914, having run a nail in the sole of his foot at some time previously not possible to determine. There was apparently locking of the jaws three days before admission, at which time the muscles of the neck and back were rigid. The wound on the sole of the foot was opened and dressed. April 16, 5,000 units of antitoxin were given intraspinally, 10,000 intravenously and 3,000 intramuscularly. The child's condition gradually improved, and he was discharged cured about two weeks after admission.

Case 8.—D. R., boy, aged 10 years, a patient of Dr. Ramsdell of White Plains, complained, Sept. 14, 1914, of pain in the back and slight stiffness of the jaw and of left arm. This child was vaccinated August 17. August 31, the vaccination wound not having been dressed for nine days, was in an unfavorable condition, there being considerable pus at the site of vaccination and swelling of the arm. A shield was later applied, on the mother's initiative. There was a further history of injury to the wound on several occasions. The incubation of the disease could not, therefore, be determined. The symptoms of tetanus increased until September 18, when the patient was given an intraspinal injection of 5,000 units of antitoxin and 45,000 units (through a misunderstanding) intravenously. Following this, there was a marked exaggeration of all the symptoms; a rise of temperature and opisthotonos, lasting about forty-eight hours. The patient gradually improved and was discharged cured in two weeks.

Case 9.—Boy, aged 6 years, a patient of Dr. Joseph Wheelwright, gave a history of trauma nine days before the locking of the jaws. Forty-eight hours later an intraspinal injection of 5,000 units and intravenous injection of 10,000 units of antitoxin were given. Subsequently this was repeated. The case was a very severe one with many convulsions, and the patient recovered fully in the fourth week.

Case 10.—A., male, at St. Vincent's Hospital, following a traumatic amputation of finger fourteen days previously, developed severe spasms of the abdominal muscles; later his jaw became locked and the rigidity was general; there were a number of convulsions. Thirty-six hours after the development of symptoms, 5,000 units of antitoxin were given intraspinally and 10,000 intravenously. There was marked anaphylaxis immediately following the injection, with urticaria covering the entire body and suggestion of edema of the glottis and lungs. This passed away shortly after the administration of a large dose of epinephrin. The intraspinal dose was repeated forty-eight hours afterward, as the patient had grown worse and had had a number of convulsions. The serum reaction following this was not so severe as in the first instance. Improvement in symptoms began to show in two or three days, the patient making a perfect recovery from his tetanus, but developed mental symptoms consisting of intermittent attacks of acute mania and delusions of persecution. After a number of weeks this completely disappeared and his condition was normal.

Case 11.—T. D., woman, aged 30 years, was seen by Drs. William H. Ross and H. E. Chauvin of Brentwood, N. Y., September 30, 1914. She had given birth to a child two weeks previously in very dirty surroundings. The symptoms of tetanus were very marked, and many convulsions continued for five days. Two days after the onset of symptoms, 10,000 units of antitoxin were given intraspinally and 5,000 intravenously; the later dose was repeated three times in three successive days. The patient was discharged cured except for a slight trismus which lasted for three days longer, October 11.

CASE 12.—R. W., boy, aged 11 years, was seen by the physicians mentioned above, Sept. 6, 1914. There was a wound over one patella, received eleven days previously. Five thousand units of antitoxin were given intraspinally and 5,000 intravenously on the day following the development of symptoms. The intravenous dose was repeated. Eight convulsions occurred during the first three days, the temperature running high during this time. The patient was discharged cured eight days after admission.

CASE 13.—W. M., man, aged 20, seen by the same physicians Jan. 3, 1915, had received a punctured wound of the instep three weeks previously. There was complete trismus and stiffness of the whole body. Ten thousand units of antitoxin were given intraspinally and 5,000 intravenously the day after the symptoms were noted. The intravenous injection was repeated the next day. The patient was discharged cured in two weeks.

CASE 14.—M. G., woman, aged 22, gave no history of traumatism. Four days before admission to the Lebanon Hospital, there was slight rigidity of the neck and difficulty in opening the mouth. The next day the jaws were completely locked. On the day before admission she had general convulsions. On the day following admission, five days after the onset of symptoms, she was given 5,000 units of antitoxin intravenously and 750 units intraspinally. On the second and third days she was given 5,000 units intraspinally under an anesthetic. The patient also received injections of magnesium sulphate (25 per cent.) subcutaneously and intramuscularly three times a day in doses of 30 c.c. for seventeen days, without apparent relaxing effect. The course of the disease was rather protracted with many convulsions. The patient was discharged cured seven weeks after admission.

CASE 15.—L. M., male, aged 18 years, was admitted to St. Peter's Hospital, March 27, 1915, with a crushed and lacerated wound of the great toe. The wound was immediately disinfected and properly dressed. March 30, the tip of the toe sloughed off. April 6, the patient had a severe chill and complained of sore throat. There was noted a slight stiffness of the jaw. In the afternoon there were marked stiffness of the back, and occasional slight convulsions when the patient was disturbed. Twenty thousand units of tetanus antitoxin were given intraspinally four hours after the occurrence of the chill. On the 7th, the symptoms increased in severity, convulsions occurring on the slightest irritation. There were marked opisthotonos and rigidity. Ten thousand units of antitoxin were given intraspinally under an anesthetic. On the 8th, the patient's condition was about the same. Ten thousand units of antitoxin were given intravenously. After the tenth day, the convulsions stopped; the rigidity continued some time longer. April 22, the patient was up and about with slight rigidity. He was discharged cured a few days later.

CASE 16.—M. S., man, aged 24, admitted to Bellevue Hospital Feb. 4, 1915, with very indefinite history, was said to have run a splinter into his foot three weeks previously. Two days before admission he complained of great pain in his back and neck, which was stiff; later he could not open his mouth. On examination the day after admission, it was found that his jaw was markedly locked, the abdominal muscles of a boardlike rigidity, and the back slightly arched. He was given 5,000 units of antitoxin in the spinal canal and 10,000 in the vein. The intraspinal dose was repeated two days later. The symptoms increased in severity for a day or two, frequent tonic spasms causing the patient to cry out with pain. After a few days all symptoms began to ameliorate, and he was completely well in about two weeks.

FATAL CASES

CASE 17.—O. R., man, aged 34, was admitted to Bellevue Hospital, Nov. 5, 1914, for a lacerated wound of the sole of the foot, which, although treated, became infected with a foul-smelling, purulent discharge. November 12, seven days later, the patient complained of difficulty in swallowing, and the jaws were stiff. He received 1,500 units of antitoxin intramuscularly, and twenty-four hours later, 10,000 units intraspinally and 10,000 intravenously. November 14, the temperature was lower, the jaws less stiff and the general condition improved, when the patient became markedly cyanotic, went into a condition of status epilepticus and died in twenty minutes. No necropsy was held. The exact reason for the sudden death of this patient, when the course of the disease had apparently been arrested, is by no means easy of explanation.

CASE 18.—J. O., man, aged 32, admitted to St. Peter's Hospital, Nov. 13, 1914, had stepped on a rusty nail, November 1. Seven days later, his jaw became stiff. This stiffness increased until the time of admission, when his teeth could hardly be separated. The muscles of the back and neck were stiff. November 13, five days after the onset of symptoms, he received 6,000 units of antitoxin intraspinally and 5,000 intramuscularly, the next day, 5,000 intramuscularly and 5,000 intravenously, and on the following day, 5,000 units intravenously and 7,000 intramuscularly. The patient had tonic and clonic convulsions in great numbers throughout the course of his illness. On the day before his death, the tonicity of the neck, jaws and abdomen had greatly diminished. He died following a convulsion, November 17. The short incubation in this case and long delay before beginning treatment are sufficient reasons for the failure of the antitoxin to save this patient's life.

CASE 19.—E. C., boy, aged 13 years, admitted to Bellevue Hospital, June 30, 1914, fourteen days previously had fallen and cut his head. Eleven days later he had abdominal pains and vomiting, which were regarded as due to appendicitis. On admission to the hospital he had marked opisthotonos, locked jaws and inability to swallow. A convulsion occurred on the slightest disturbance. He received 10,000 units of antitoxin intraspinally and 10,000 units intramuscularly. The patient's condition grew worse from the time of his admission and he died within twenty-four hours. The disease had evidently progressed too far to be influenced by antitoxin.

CASE 20.—W. R., physician, aged 53, was admitted to the French Hospital for herniotomy, which was performed, April 25. May 3, the patient complained that his neck felt stiff; May 4, this symptom was more pronounced and there was some rigidity of the jaw. Toward evening he could not open his mouth fully. He was given about 9,000 units of antitoxin intramuscularly. May 5, he had a general convulsion and became quite cyanotic; this was repeated twice, convulsions lasting about ten minutes. Five thousand units of antitoxin were given intraspinally and 15,000 intravenously. May 6, the patient had four convulsions, one lasting fifteen minutes. Five thousand units of antitoxin were given intraspinally. May 7, there were no further convulsions. The patient was able to take fluids by mouth, and there was much less rigidity. At 8 o'clock in the evening he had a sudden attack of pulmonary edema and rise of temperature. Later there were signs of acute cardiac dilatation. He died on the morning of May 8. This patient was very stout, and had chronic bronchitis and recurring attacks of asthma.

In judging the effect of antitoxin given intraspinally in this series of cases, it must be remembered that the patients were not selected, but that every case of tetanus reported was given the benefit of the treatment regardless of the clinical condition. The series, therefore, may be said to be fairly representative of the type of the disease occurring in and about the city of New York. A few of these patients would undoubtedly have recovered if the intraspinal injection of antitoxin had not been given or, indeed, without any treatment other than symptomatic. The results obtained, however, in the saving of life are so much more favorable than those in previous years, when large doses of antitoxin were recommended to be given by the intravenous and subcutaneous methods, that there can be no reasonable doubt that the low death rate, 20 per cent., here obtained was largely due to intraspinal dosage.

THE USE OF KAOLIN TO REMOVE BACTERIA FROM THE THROAT AND NOSE *

L. HEKTOEN, M.D.
AND
B. RAPPAPORT, M.D.
CHICAGO

Kaolin is used in immunologic and other investigations on account of its great adsorptive powers. The idea occurred to us that, on account of this adsorptive power, kaolin might be of use in removing bacteria from the nose and throat, especially in diphtheria carriers. Accordingly, with the cooperation of Dr. George H. Weaver, tests have been made in suitable cases in the Durand Hospital of the Memorial Institute for Infectious Diseases.

We have found that, when properly applied, kaolin in the form of a dry powder removes not only diphtheria bacilli, but also practically all bacteria from the nose in the course of from three to four days. For this purpose the kaolin is blown into the nose six or seven times a day at two-hour intervals by means of a rubber bulb attached to a glass tube, the free end of which tapers a little. The insufflation is repeated several times at each treatment. The success of this treatment appears to depend largely on the free and thorough distribution of kaolin over the nasal surfaces. In cases of more or less obstruction of the nasal passages, the removal of bacteria by kaolin insufflation is more difficult.

In order to secure the most thorough application of kaolin to the mucous membrane of the throat, patients, if old enough, are instructed to swallow as slowly as possible one-third teaspoonful of kaolin four or five times an hour during the day. In the case of adults and older children who are anxious to get rid of diphtheria bacilli, this method, which has been selected after trial of several others, involves no special difficulty. In the case of small children, it is more difficult to apply enough kaolin, and the plan of mixing the kaolin with sugar in the form of tablets is being considered. In a number of cases, in some of which there were a great many diphtheria bacilli in the throat, complete and apparently permanent removal has been accomplished by means of kaolin in the way described in from two to four days, the throat to a large extent being freed from all bacteria.

We have found also that the insufflation of kaolin into the nose in cases of rhinitis in scarlet fever appears to improve the condition rapidly and to remove streptococci and other bacteria quite promptly.

We have not found kaolin to be irritative; when taken into the mouth it gives rise to a feeling of grittiness.

It seems, then, that kaolin, and probably also other substances of a similar nature, may prove of value in removing bacteria from various surfaces of the body by virtue of mechanical adsorption. This may prove of advantage, not only in carriers, but also in conditions of acute infection. Our experience indicates that by means of kaolin, diphtheria bacilli and other bacteria are removed quite easily, especially from the nose.

SODIUM FLUORID POISONING *

J. N. STANTON, M.D.
AND
MAX KAHN, PH.D., M.D.
PITTSBURGH

Several cases of hydrofluoric acid poisoning have been reported.[1] Two well-known chemists were killed by the inhalation of the poisonous fumes of this acid.[2] But so far as we are aware, there is no case of sodium fluorid poisoning on record. The toxicologic effects of the metallic fluorids were studied by Rabuteau,[3] Müller,[4] Tappeiner,[5] Schulz,[6] Hewelke,[7] Siegfried[8] and Schwyzer.[9] Witthaus calls attention to the fact that notwithstanding its toxicity, sodium fluorid is used as a food preservative.

From the pharmacologic experiments it is clear that sodium fluorid is a general protoplasmic poison. It is strongly irritant to mucous membranes and usually produces corrosions. Owing to the fact that the fluorid ion precipitates soluble calcium salts, its toxic effect is similar to that of the oxalate ion. In mammals it causes salivation, gastro-enteritis, dyspnea, convulsions and stoppage of respiration and heart.[10] The fluorids on administration are deposited in the bones, which usually become white and brittle and contain crystals of calcium fluorid. It is well to call attention to the fact that fluorin, in very small traces, is a normal constituent of bone, teeth, milk, eggs, etc.[11]

Intravenous injections of from 0.05 to 0.1 gm. sodium fluorid per kilogram of dog are fatal. A 0.03 per cent. solution of this fluorid will destroy epithelium. A frog will be killed by 0.040 gm. of this salt.

The following is the history of a case of sodium fluorid poisoning:

V. R., girl, aged 19 months, swallowed some of "Peterman's Roach Food" which, according to the label on the box, contains from 40 to 50 per cent. of sodium fluorid. The child immediately began to feel bad and vomited. The child had partaken of food just before she swallowed the poison. The pulse was normal and the temperature normal. A tube was inserted into the stomach of the child and the stomach was washed repeatedly with a solution of lime water and calcium chlorid. About a gallon of lime water and calcium chlorid was used in this operation. It was noticed that there was some bleeding from the gums when the tube was inserted.

The child seemed to feel well after the stomach wash. A specimen of urine collected the following day showed a trace of acetone, but no albumin or casts. A few white blood cells were found. Seventy-two hours later the urine showed albumin, a few granular casts and some red and white blood cells. Fluorin was present in both specimens of urine, which were evaporated and tested according to the method given by Witthaus.

On the third day the temperature rose to 102 F., and the pulse became rapid. Analysis of a catheterized specimen of urine showed no albumin. A few white blood cells and a trace of acetone were present. This specimen did not contain any fluorin. The blood count revealed: hemoglobin,

74 per cent.; red blood cells, 4,000,000; white blood cells, 15,200; polynuclears, 69 per cent.; lymphocytes, 22 per cent.; large mononuclears, 8 per cent.; eosinophils, 1 per cent. Microcytes were present. High colonic irrigation was resorted to, and the patient was given a dose of castor oil. The temperature fell on the following day and the pulse became normal. On the fourth day a specimen of urine was collected. It was acid in reaction, contained a trace of albumin, and gave quite a heavy acetone reaction. Microscopically a few red and white blood cells were present, but no casts. The urine did not reduce Fehling's solution, and did not react positively for diacetic acid. No fluorin could be demonstrated in this specimen. Since that time, examinations of a number of specimens of urine showed no albumin and but a very faint trace of acetone. On the eighth day the child was taken home from the hospital, to all appearances entirely well.

GANGRENOUS APPENDICITIS ON THE LEFT SIDE

A CASE OF VISCERAL TRANSPOSITION

W. B. Palamountain, M.D., Colfax, Wash.

Gangrenous appendicitis occurring with visceral transposition is so uncommon that it is thought well to report the following case:

A married woman, aged 18, who had had no pregnancies and whose previous history was negative, had irregular menses during the past year. Jan. 30, 1915, she took a course of calomel. Next day she felt well. At 11 p. m. she was awakened by a sudden, severe abdominal pain, of a cramping, colicky nature, in the midabdomen, which continued all night and was accompanied by vomiting. Pain continued all next day, but became localized in the left iliac region and there remained constant with occasional vomiting. She took castor oil and applied hot applications with no relief.

February 2 she was driven to town. The trip took four hours. She vomited once and suffered much. Examination forty hours after onset revealed a medium-sized woman, plainly in severe pain; she leaned to the left side and kept the left thigh flexed. The menses were two days overtime. Temperature was 99½, pulse 120. The abdomen was full and tympanitic. The right side of the abdomen was not tender, and there was little or no muscle spasm. The patient was extremely tender and sensitive over the left side of the abdomen; percussion was almost unbearable; muscle spasm was pronounced. The patient complained of constant pain over the left lower abdomen. Urination and urine were normal.

The uterus was in second degree retroversion, a little large and softer than normal. There was no discoloration of the vaginal membranes. The cervix was soft. Deep palpation of the right adnexal region was not painful. There was some pain in the left adnexal region, and suspicion of a mass felt high up on left side. The breasts were normal.

A diagnosis of probable tubal gestation was made, and operation advised. This was not accepted till next morning, when, owing to increase in pain and fever, and after consultation, operation was accepted and performed fifty-eight hours after onset.

A median incision disclosed the intestines distended and a mass in the left iliac region and no sigmoid found there. The sigmoid was found in the right side and entered the pelvis from that side. The ascending colon and ileum were on the left side, and a gangrenous and perforated appendix lay under the cecum on the pelvic brim. The great omentum surrounded the cecum and appendix and was gangrenous, forming a mass the size of a goose egg. Peritonitis was already present. The appendix, greenish-black and partly liquefied, was removed and drainage inserted. No exploration of the upper abdomen was made, but later by palpation the liver was located on the left side and the apex beat of the heart was in the right fourth interspace. The case, therefore, was one of complete situs transversus. No pregnancy existed. Death occurred fifteen days later from peritonitis.

Special Article

PRACTICAL PHARMACOLOGY *

(Continued from page 1913)

XXIII

EVACUANTS—(*Continued*)

3. *EVACUANTS ACTING ON THE SMALL AND LARGE INTESTINES*

The Mercurials

The insoluble purgative mercurials, including calomel (mild mercurous chlorid), mass of mercury, (blue mass), and mercury with chalk (gray powder), have little action on the stomach unless their passage through it is delayed; their action on the intestine is mildly irritant, increasing peristalsis directly, and possibly increasing the secretion of the intestinal glands, thereby promoting peristalsis indirectly and causing soft stools with little or no pain, or with larger doses causing watery stools with some colic.

Only a small part of the dose of a mercurial is absorbed when evacuation is induced promptly, but when there is interference with the movement of the intestinal contents the mercurials are absorbed. If there is great interference with the passage of the intestinal contents after a large dose of calomel, or other mercurial salt, diuresis is induced. This interference is sometimes secured by administering opium or morphin with small doses of calomel, but if it occurs after large doses toxic symptoms referable to the irritant action of mercury on the kidneys may result.

Other steps should be taken to induce purgation should one of the mercurials fail to act, except when small doses are taken for their diuretic action.

The mercurials were long supposed to increase the secretion of bile, but this error arose from the fact that they protect the bile from decomposition by the intestinal flora, and prevent its absorption by hastening its passage through the intestines, so that it appears in the stools, if the dose be large enough to cause liquid evacuations. The green color of the stools in such cases is sometimes attributed to bile, but it is probably due to the formation of a sulphid of mercury.

There is much uncertainty concerning the reputed antiseptic action of calomel in the intestine. It does not destroy the bacteria in all probability, or greatly inhibit their growth during their stay in the intestine, but great numbers are removed during the purgation. It is a matter of common experience, however, that the condition commonly called "biliousness" (which does not require further description) is often relieved far more effectually even by a merely laxative dose of calomel, than by other evacuants which act as promptly as calomel. On the other hand, many persons find that headaches which are attributed to the products of intestinal putrefaction resulting from bacterial activity, are relieved quite as well by a quickly acting saline purge as by calomel. This does not disprove the claim that calomel has an especial action in the condition mentioned, for obviously, an active cathartic which sweeps out the intestinal contents with a large amount of water in a very short time must remove undigested and putrefying food and enormous numbers of bacteria, and thus give relief, but stress is laid on the fact that a mildly acting dose of calomel or other mercurial, which causes only a soft, not liquid stool, gives decided relief from certain forms of headaches which are not relieved by vegetable laxatives.

---

* This is the twenty-third of a series of articles on useful drugs—on practical pharmacology for the general practitioner. As soon as completed, these articles, elaborated by additional subjects, will be published in book form.

Calomel often fails to relieve the diarrhea of infants which is caused by bacterial activity, but this does not prove that calomel is not bactericidal. The hypersecretion of mucus in such conditions affords excellent opportunities for the multiplication of bacteria after the calomel has passed through the intestine, and it is not feasible to keep the entire intestinal canal supplied with the drug, since so much would have to be used that systemic poisoning would ensue.[1]

Calomel is more useful in preventing the development of the more severe symptoms when taken in time, than in curing them after full development.

Mercury with chalk is less irritating than calomel; the chalk is said to interfere with peristalsis sometimes.

Calomel has little action on the uterus and is therefore not contraindicated in pregnancy. The action of blue mass is much like that of mercury and chalk.

THERAPEUTICS

The therapeutic indications for the use of the mercurial purgatives is sufficiently indicated in the discussion of their actions. Calomel, blue mass or mercury with chalk may be used when there is need for a mild laxative, or in somewhat larger doses when a cathartic is required. Headache due to intestinal putrefaction, the condition called "biliousness," putrefactive diarrhea, and in fact any condition attended with intestinal putrefaction, may serve as an indication for one of the mercurial purgatives unless there is a specific contraindication for their use.

DOSAGE

Calomel was used formerly in enormous doses for a variety of conditions and salivation was a common result, but with a more rational and more limited use of calomel this condition is now rare.

As a result of the reaction following the use of such large doses of calomel physicians went almost to an opposite extreme, and minute, but frequently repeated doses came into favor. If one desires to use such small doses from 3 to 5 mg. (1/20 to 1/10 grain) may be given every fifteen minutes until ten doses are taken. This method of administration sometimes induces nausea without any apparent advantage in the action, but it is possible that it secures a more prolonged, or more frequently repeated, antiseptic action in the intestine.

A dose of from 30 to 60 mg. (½ to 1 grain) will often act as a laxative after from eight to twelve hours, but it is preferable to give a saline laxative about four to six hours after administering the calomel unless purgation has taken place. Doses of from 0.15 to 0.30 gm. (2½ to 5 grains) of calomel induce severe purgation with copious watery stools attended with severe griping and a considerable degree of nausea, but such doses have little advantage over smaller doses followed by a saline purgative which causes an equally active purgation with much less discomfort.

From 8 to 15 mg. (⅛ to ¼ grain) of calomel given to a child at the beginning of an attack of diarrhea, and followed by doses of 5 mg. (1/10 grain) twice a day for several days, will often avert more serious symptoms.

It is probable that doses of calomel larger than 0.12 gm. (2 grains) are never required for an adult; should this fail to cause purgation dependence should be placed on other evacuants, particularly the salines.

Sodium bicarbonate is commonly added to calomel under the mistaken idea that it is necessary to combine an alkali with the mercurous salt to prevent its conversion into a mercuric salt by the gastric juice. The amount of sodium bicarbonate usually employed is wholly inadequate to neutralize more than a small part of the gastric juice in the stomach, and no such change takes place when calomel is subjected to the action of the gastric juice without neutralization.

Mass of mercury or mercury with chalk may be given in doses of 0.25 gm. (4 grains).*

SALINE EVACUANTS

When a concentrated solution of one of the slightly diffusable salts is taken into the stomach it becomes diluted with the gastric secretion, or, if the stomach was previously empty, it withdraws fluid from the cells of the stomach, causing irritation, with nausea and vomiting at times.

The rate at which this dilution in the stomach occurs in the absence of a sufficient amount of fluid previously present, will depend to a considerable degree on the relative amount of fluid in the blood and tissues. If they contain an abundance of water, secretion will be active as a rule, and when the solution of the salt has become fairly dilute it will pass into the intestine, but if the blood and tissues contain relatively little water gastric secretion is slow and nausea and vomiting may result. This is best illustrated by the protocols of two laboratory experiments (hitherto unpublished).

> Two dogs, A. and B., received an equal amount of sodium sulphate. Dog A. received the salt in concentrated solution after having been deprived of water for twenty-four hours, and vomited within about five minutes; he even refused water owing to nausea, but when enough water was passed through a tube into his stomach to dilute the salt somewhat, he drank water almost immediately. Dog B. was given the same amount of salt in dilute solution after having had the usual allowance of water; he showed no signs of nausea, and ate food at once (showing absence of nausea).

When a solution of salt has passed into the intestine it retains its water of solution until its concentration has been so reduced as to be approximately equal to that of the blood, the distention of the intestine by the fluid causing peristalsis, the action being exerted in the small and large intestine.

The salts of this group are not absolutely nonabsorbable, and when peristalsis is prevented by any means the solutions may be absorbed into the circulation completely. If the absorption takes place, as it always does to some slight extent, the salt is excreted by the kidney, and it may induce diuresis if the absorption has been sufficiently rapid, for the renal epithelium, in marked contrast to that of the intestine, is readily permeable to most of these salts.

Occasionally, large dc [illegible] sulphate have been absorbed in [illegible] of the bowel more rapidly than they could be eliminated by the kidney, and have given rise to symptoms of poisoning, and in a few instances death has resulted, but this accident is not to be feared except when obstruction of the intestine exists, and, of course, no purgative should be given in such conditions.

---

[1] For a discussion of the subject of intestinal antisepsis see Harris, Norman M.: Intestinal Antisepsis, The Journal A. M. A., Oct. 12, 1912, p. 1344.

* Owing to lack of space the materia medica of this group is omitted from The Journal. It will be included when this series is published in book form.

When magnesium sulphate (Epsom salt) is absorbed rapidly, or is injected intravenously, in sufficient amounts, it depresses the nervous system and induces complete narcosis with muscular relaxation. The depressant action following the subcutaneous injection is now being utilized in the treatment of the chronic form of tetanus with reported success. The absorption from the intestine is probably too slow in any case to induce serious poisoning unless the kidneys are diseased or marked depression of the central nervous system previously exists. The other purgative salts are devoid of toxic actions after absorption. Magnesium citrate should be open to the same objection as the sulphate, but no cases of poisoning have been reported after its use, so far as we are aware.

The precise mechanism of the purgation induced by these salts is not understood fully, but there is no reason to doubt that their action results largely from their capacity for retaining water and thus distending the bowel. This also explains why concentrated solutions require so much longer time than dilute before causing purgation, and twenty hours may elapse before their effect is induced, whereas dilute solutions are commonly effective within three hours.

The purgative salts have a disagreeably bitter taste, and not infrequently concentrated solutions are taken in order to lessen the time required to drink them; when they are taken in this way a glass of water should be taken immediately to dilute them in the stomach, unless the removal of an excess of water from the tissues is the object in view, in which case concentrated solutions are usually employed.

It is probable that moderately dilute solutions would be more serviceable in such cases than the concentrated ones commonly used. The amount of fluid which can be removed by purgation is very much greater than that required for the moderate dilution of the salt, and the absence of gastric disturbance and the much more rapid effect of the dilute solutions suggest that they might be employed even in dropsical conditions.

Magnesium sulphate is partly converted into carbonate in the intestine, and the liberated sulphuric acid combines with the alkalies which are absorbed and excreted in the urine; thus depriving the body of them. This becomes a matter of importance when the salt is administered continuously for some time, and it is customary in such cases to administer sodium bicarbonate to make up the deficiency. This loss of alkali does not occur with the use of sodium sulphate or the other purgative salts.

The administration of the sulphates (Epsom salt or sodium sulphate) is followed by the formation of some hydrogen sulphid in the small intestine, and this may give rise to some discomfort, with rumbling.

The insoluble magnesium carbonate and the oxid, or calcined magnesia, are partly converted in the stomach into the soluble chlorid, and in the small intestine partly into the soluble bicarbonate. Should they fail to undergo the change they do not cause purgation, and an accumulation of the insoluble carbonate may occur after large doses and cause intestinal obstruction.

Magnesium oxid has an advantage over the carbonate in that it does not yield carbon dioxid gas when neutralized in the stomach. The oxid and carbonate have the advantage over the soluble salts of this group, being tasteless, and requiring a less bulky dose.

Potassium citrate and bitartrate are absorbed somewhat more rapidly than the other purgative salts, so that small doses induce diuresis without purgation, while large doses cause both, but at best they are only mild laxatives, rarely giving rise to watery stools, but they are active diuretics.

Sodium chlorid or the ordinary table salt in proper dilution is also useful as a laxative and may at times advantageously replace other objectionably bitter salines. The dose, about an even teaspoonful (from 4 to 5 gm. or about 60 grains), should be dissolved in half a liter (1 pint) or more of water and taken on an empty stomach.

Various acid fruits are mildly laxative, partly because of the citric and malic acids which form citrates and malates in the intestine, and partly because of their cellulose, pectin and sugars which are in part indigestible and absorb liquid, thus increasing the bulk of the intestinal contents in much the same way that the purgative salts do.

THERAPEUTIC USES

The uses of the saline laxatives are indicated largely in the discussion of their actions. They are useful when for any reason a rapid evacuation of the bowels is indicated, as in poisoning by slowly absorbable substances which cannot be removed from the stomach; to remove bacteria and fermenting masses of food; to remove dropsical effusions, and in simple constipation.

They have an especial usefulness in that they do not cause irritation when used in dilute solutions.

This would be an appropriate place to discuss the use of purgative mineral waters were it not for the fact that there is no obvious advantage in their use. There can be little doubt that the extraordinary reputation enjoyed by many of these waters depends on the success attained in the treatment of patients at the springs, where special attention is given to all the habits of life, and where only the most pleasant conditions obtain. There is no satisfactory evidence that the ordinary purgative mineral waters have any important action not possessed by a simple solution of the same salts made artificially, and, in fact, many of the mineral purgative waters are more or less artificial, since some are mixtures of waters from different springs while others consist of evaporated spring water, and during the process of evaporation changes occur in the salts present.

One especial advantage which natural mineral waters have over the solutions of purgative salts as they are too often taken is that they are very dilute, and the patient is thus required to take a fairly large amount of water with them. This advantage can be secured so easily, however, by attention to the proper dilution of purgative salts that it is not sufficient to justify the expense of the natural waters.

Magnesium sulphate is largely used in obesity because the magnesium ion combines in part in the intestine with fatty acids which are thus prevented from being absorbed. The tasteless magnesium oxid and carbonate are often used as laxatives in children, especially when it is desired to neutralize the hyperacidity of the stomach.

The normal sodium phosphate is alkaline in reaction and when it is desired to increase the acidity of the urine the acid phosphate, NaH_2PO_4, is to be preferred, or the official di-sodium phosphate may be used adding about three times as much dilute phosphoric acid to it.

A concentrated solution of magnesium sulphate is used as a local application in inflammatory conditions.

DOSAGE

The amount of the several salines required to accomplish a given purpose depends largely on accompanying factors, such as the degree of dilution and the susceptibility of the individual, which vary considerably.

Epsom salt or magnesium sulphate. the effervescent preparation of this substance and sodium sulphate, or Glauber's salt, are usually given in doses of 16 gm. (240 grains) or more, dissolved in from one-half to a full tumbler of cold water. Potassium and sodium tartrate, or Rochelle salt, is given in doses of 8 gm. (120 grains). Sodium chlorid, or ordinary "table salt," and sodium phosphate are given in doses of approximately 4 gm. (60 grains), well diluted with water. The effervescent preparation of sodium phosphate is usually given in double the dose of the simple salt or about 8 gm. (120 grains).

Magnesium oxid—heavy or light—is given in doses of 2 gm. (30 grains) and the carbonate in somewhat larger amounts, 3 gm. (or 45 grains). Because of the fact that these two substances are insoluble in water they must be administered in the form of mixtures with water or in the case of the heavy magnesium oxid the dry powder can be placed on the tongue and washed down with cold water.

The solution of magnesium citrate is usually dispensed in bottles sufficient for one dose which is drunk as an effervescing draught. Potassium bitartrate, one of the more agreeable of the salines because of its acid taste, is given in doses of 2 gm. (30 grains) mixed with water. Potassium citrate may be given in about the same dose 2 gm. (30 grains) and the effervescent preparation in double this dose—4 gm. (60 grains).

The administration of the salines is somewhat simplified in that their action is enhanced by the presence of water and that, whether water-soluble or not, they are preferably given with copious draughts of water.

Alkaloidal Evacuants

Physostigmin

It is apparent from the discussion of the physiology of the gastro-intestinal movements that any drug which stimulates the parasympathetic nerves (vagus and erigens) will cause intestinal peristalsis, or contraction of the muscles of the intestinal walls.

We have a number of agents which stimulate the endings of these nerves, or which increase their excitability to the normal stimuli which reach them through the blood, but these drugs have other actions which usually overshadow their actions on the intestine and prevent their use as evacuants.

Pilocarpin and physostigmin stimulate the vagus and erigens, and induce active movements, not only in the intestine but also in the stomach and uterus. Physostigmin probably acts directly on the smooth muscle of the intestine rendering it hyperexcitable to normal stimuli, and thereby promoting peristalsis. Large doses cause tonic ring-like contractions of the intestine and interfere with the passage of the contents.

Large doses of physostigmin cause violent uterine contractions which may be tonic in character.

There seems to be little reason for the use of any of the pharmaceutic preparations of physostigma, since they contain eseridin and calabarin in variable amounts in addition to physostigmin. Eseridin resembles physostigmin in its physiologic actions, but it is weaker, and calabarin has a strychnin-like action.

Physostigmin sulphate is hygroscopic and the solution decomposes rapidly with the formation of a ruby-red substance known as red resin. The salicylate is soluble in about 150 parts of water. It is somewhat more stable than the sulphate in solution but it also undergoes the same decomposition.

THERAPEUTIC USES

The actions of physostigmin on the intestine are usually overshadowed by its effects on the central nervous system, and it is far from satisfactory as an evacuant, its use as such appearing to depend rather on a forlorn hope in the search for a dependable purgative after abdominal operations. The use in man has been encouraged perhaps by the observation that it is a very much more valuable purgative for the herbivora.

The indication for which physostigmin is used as a purgative is atony of the intestine. It should not be used in the presence of inflammation of the intestine or when there is mechanical obstruction. The local and systemic actions of physostigmin are counteracted by atropin in doses of 1 mg. ($\frac{1}{60}$ grain), which may be repeated once or twice if necessary.

DOSAGE

Physostigmin salicylate is used as an evacuant in doses of 1 mg. ($\frac{1}{60}$ grain) and doses of even 2 mg. ($\frac{1}{30}$ grain) are sometimes given, but Sollmann states that such doses are somewhat dangerous, this being especially true in the presence of depression of the central nervous system.

Atropin; Strychnin

Atropin and strychnin are never used alone as evacuants, but both of them are added to other substances which induce purgation, and atropin is used to relieve spasm of the intestine which interferes with the passage of the intestinal contents.

Small doses of atropin are said to stimulate Auerbach's plexus, while large doses depress it, and all doses which have any effect depress the parasympathetic (vagus and erigens) endings in the intestine. This is of benefit when overstimulation causes tonic contraction instead of normal peristaltic waves.

There is a possible disadvantage in the long-continued use of even very small doses of atropin which is generally overlooked or disregarded, but which is worth considering. Atropin depresses the vagus endings in all of the organs which it supplies, and even small doses tend to abolish those parts of the gastric, pancreatic and biliary secretions which are under nervous control. It is certain that the minute amount of atropin ($\frac{1}{10}$ mg.—$\frac{1}{650}$ grain) commonly used with aloin in laxative pills has no very pronounced action on these secretions when a single dose is taken, but, on the other hand, we have no knowledge of the effects of its long-continued use, and in the absence of definite advantages it would be better to omit it when laxative pills are to be taken for prolonged periods.

Strychnin is used in doses of 1 mg. ($\frac{1}{60}$ grain), which are correspondingly larger than those of atropin, and it seems to be useful through its stimulation of Auerbach's plexus.

Extremely small doses of nicotin stimulate, large doses paralyze, the ganglia of the enteric system, and it is a matter of common observation that smoking often promotes peristalsis. Nicotin is not used therapeutically, however, for this purpose.

A TEST OF PHYSICAL FITNESS

The conservation of national vitality has become a popular theme in this country. It is a part of a still greater problem which is designated as national efficiency. The old fatalistic belief in the inevitable occurrence of ill health and early death in certain instances has given way to the rapidly growing conviction that premature death and disease are for the most part avoidable and that it is within the power of man to rid himself of many of the enemies to comfort and good health. The aim of hygiene is to approximate, with respect to health, the ideal of a life free from illness and disability of every kind.

In this effort to bring about a maximum fitness of mankind, many agencies are being brought into play. Our physical environment is being subjected to closer scrutiny; and by means of private and public regulation, a protection is frequently rendered to mankind in ways more important than that provided by the work of police or fire departments. The abatement of nuisances, inspection systems, regulation of labor and trades — these are a few reminders of the vigorous attempts at the conservation of health through public hygiene. To this may be added the improvement of the social environment and the effects of what has been called semipublic hygiene, that is, the disciplines relating to institutions and the medical profession. The diffusion of knowledge regarding the laws of health and its control, the care of individuals who are for some reason unfitted to adjust themselves to the needs of the day, along with numerous other potential agencies for bringing about health, are illustrative of the prophylactic tendencies of the times. It is being found that "philanthropy and profit are not always antagonistic." Finally, public hygiene is receiving the support of personal hygiene, without which it must remain ineffective. Here nutrition, fresh air, exercise and rest, sports, and the combat with the social diseases find their place. Some one has well remarked that the present world-wide interest in personal hygiene and physical education is not due to any startling discoveries, but to the rediscovery of the importance of truths long insisted on by the medical profession. The knowledge of the value of fresh air and good food is old. It is the application which is new.

A healthy organism calls into play almost innumerable functions, both physical and mental. How to measure the efficiency with which they are carried out and the fitness of the individual to undertake or endure them has become a problem of the day. Mental capacity has been investigated by a variety of standards, some of which have gradually become widely accepted. As an instance of how the quantity and quality of intellectual product per unit of time can be studied, we may refer to such psychologic tests as the naming of colors, cancellation, addition, mental multiplication, typewriting, grading of various performances, and exercises in English composition. The ability to accomplish set tasks of this sort varies with environmental as well as personal and hereditary conditions. The physical working capacity of the individual can likewise be measured by a variety of apparatus designed to test muscular strength.

The fitness of man involves something more than the ability to do sums or lift dumb-bells. The propaganda for health and increased vitality obviously calls for some added mode of measuring the results of supposed benefits and menaces, long-continued activities, such as physical training, gymnastics, play, athletics and good ventilation on the one hand, and fatigue-producing activities on the other. The record of the incidence of disease, the school record, the blood count, etc., are not a sufficient criterion. Among the added tests which are intended to show the beneficial or depressive effect of various conditions supposed to affect health is the "blood ptosis test."[1] This has been designed by Dr. C. Ward Crampton of the Bureau of Educational Hygiene in the New York City Department of Education to measure a function easily wearied and damaged by unhygienic influences. It is based on the fact that the vasomotor control of the splanchnic area in man experiences a change of adjustment when the body is moved from the horizontal to the upright standing position. According to Crampton, the efficiency of this control is measured by placing the subject in a horizontal position and taking the systolic pressure in the brachial artery. The subject is then required to stand, and without removal of the cuff, the blood pressure is taken in a vertical position. In a perfectly strong and vigorous subject the splanchnic vasotone will increase and the blood pressure will be found raised about 10 millimeters of mercury. In an individual weakened by dissipation, overwork, lack of sleep, or by the incidence of disease, the blood pressure will tend not to rise but to fall. It was found that in the vigorous subjects the heart rate did not increase on standing, and in the wearied subjects it increases as much as forty-four beats per minute. It was further found that this difference varied with the blood-pressure differences and in some cases took the place of the blood-pressure variation. In other words, the same subject under the same conditions would show a weakness sometimes by a decrease in blood pressure, and at other times by an increase in heart rate, and vice versa. After further observation, it was determined that a decrease of 1 millimeter of mercury had a value of an increase in heart rate of approximately two.

---

[1] Crampton, C. W.: The Blood Ptosis Test and Its Use in Experimental Work in Hygiene, Proc. Soc. Exper. Biol. and Med., 1915, xii, 119.

By taking into account both of these features and adjusting the changes in heart rate into terms of corresponding blood-pressure variations, Crampton has devised a percentage scale of vasomotor tone ratings which have been put to the test by numerous observers. Experience already shows that the measurement of the changes in the performance of the heart and the vasomotor system in different postures may reveal damages before subjective or objective symptoms are apparent. For example, the New York State Commission on Ventilation has recently reported that a very high room temperature, such as 86 F., with 80 per cent. relative humidity, produces a marked fall in the Crampton value of subjects.[2] The use of fans afforded some improvement. The new test obviously does not measure numerous important features, such as the structural condition of the heart; yet it seems likely to have considerable value in furnishing added data for the estimation of what we may, for the want of a better term, call physical fitness.

KAOLIN IN THE TREATMENT OF BACTERIA CARRIERS

Aluminum silicate, kaolinum, fuller's earth and bolus alba are various names under which the essentially same substance is familiar to physicians. In 1906, Stumpf of Wurzburg published a detailed report of his experience with it in cholera under the title "A Reliable Method of Treating Asiatic Cholera and Severe Infectious Cholera Morbus, and the Importance of Bolus Alba (Kaolin) in the Treatment of Certain Bacterial Infections." His attention was early attracted to the possible disinfecting virtues of clay by his observation that cadavers exhumed after being buried in clay soil were always in a remarkable state of preservation in comparison with those in other soil. At that time his experience with the kaolin covered eight years. He believed that it owed its efficiency in bacterial infections to its action in depriving the bacteria of a suitable culture medium while mechanically burying them alive, separating them from the mucosa and other tissues by a protecting, comparatively impermeable coating. He applied it as a remedy to extensive septic wounds, putrid leg ulcers and the like. Stumpf experimented on himself to determine the harmlessness of the finely pulverized kaolin taken internally in large amounts, and found that it was well tolerated. He administered it in cases of cholera, and found that colics and tendency to vomit were at once arrested. The dose given was 125 gm. of the most finely pulverized kaolin poured on top of half a tumbler of water. After the powder sank to the bottom of the glass, it was thoroughly stirred in with a spoon, and the whole amount taken at once or within a few minutes. After an interval of three hours, the same dose was repeated. Infants were given proportionately smaller doses.

More recently, kaolin has been given as a gastric astringent; it has been much used in the treatment of cholera and dysentery, and its harmlessness has suggested its use as a substitute for bismuth in taking Roentgen-ray pictures of the gastro-intestinal tract when bismuth cannot be tolerated. In the present European war, the physicians in the German and Austrian armies are using large amounts of kaolin to combat dysentery and cholera, and according to Stumpf,[1] the microscopic findings in the feces of the patients treated fully warrant its use. Wolff-Eisner,[2] from his experience in the war, believes that kaolin has been triumphant in the treatment of cholera. He tabulates twenty-five cases, showing almost immediate stopping of diarrhea in dysentery and typhoid after a dose of a double spoonful each of kaolin and charcoal had been taken from one to three times a day. In severer cases, the proportion of kaolin was doubled. He regards the kaolin-charcoal treatment as a kind of immunotherapy, basing his belief on Hofmeister's dictum that all the phenomena of immunity are colloid chemical reactions. He believes that the kaolin binds toxins which are beyond the reach of serotherapy. The method was applied to healthy carriers and was apparently successful, as no bacilli could be found in the stools after the treatment was administered.

Von Willuki,[3] encouraged by the use of kaolin in the treatment of cholera and dysentery by the methods advised by Stumpf, has used it in two cases of paratyphoid bacteria carriers. In both cases, following treatment with bolus alba, the organisms quickly disappeared from the stools.

Of special interest, therefore, is the note elsewhere in this issue[4] by Hektoen and Rappaport. By insufflating kaolin powder in the nose, they are able to remove the diphtheria organism as well as streptococci from the nasal mucous membranes. The swallowing of the powder is followed apparently by a rapid disappearance of the diphtheria organism from the throat. These results are significant.

THE COMPOSITION OF DIARRHEAL STOOLS

A diarrheal stool is an obvious symptom of some disturbance in the functions of the organism. How serious or significant the diarrhea may be usually depends on a number of attending circumstances. One can easily postulate a variety of conditions, each of which might lead to a copious or abnormal evacuation of the bowel, yet be of quite unlike moment to the organism in which they occur. A nervous reaction may thus lead to an accelerated peristalsis and result in an increased defecation without further import; the presence of toxic micro-organisms in the intestine may provoke undue secretion followed by abundant evacuations and loss of body constituents which would ordinarily be retained or reabsorbed; abnormal digestive functions with attendant putrefaction and fermentation may produce a diarrhea with the enforced loss of what would be nutrient products under normal alimentary conditions.

It seems almost unbelievable that so little is known respecting the relation of the chemical composition of abnormal stools to the general nutritive welfare of the individual. The feces are frequently the objects of careful scrutiny macroscopically and microscopically with the object of discovering some offensive invader of the alimentary canal or some harmful foreign substance. Professor Holt and his collaborators[1] at the Babies' Hospital and the Rockefeller Institute in New York have lately called attention to the paucity of data regarding the diarrheal stools of infants in comparison with those which were normal.

Superficially, one might assume that very loose stools differ from normal ones only in that they contain more water. The new investigations[1] show how far from correct such a haphazard generalization may be. Not only do diarrheal stools contain a large amount of water, but also the quantity of dry matter lost daily is much greater than that lost in stools of normal consistency. The fats in particular vary in most cases directly with the amount of water leaving by the bowel. Thus, on an average, the loss of fatty matter in the normal feces of infants at the Babies' Hospital was 12 per cent.; in the loose stools it reached 40 per cent. The nitrogenous substance also may reach an amount equal to two and a half times that lost in normal stools. A considerable amount of it is presumably not derived from the food, but represents portions drained away from the body in the intestinal secretions. This is attended by a withdrawal of inorganic salts from the body under conditions in which it might never be suspected but for the evidence secured by chemical analysis.

There are further facts which point to suggestions in the direction of dietotherapy. An equivalent of over 80 per cent. of the intake of salts in the diet may disappear with diarrheal feces. This may include, in individual cases, much of the calcium and all of the magnesium of the diet. Chlorin, potassium and sodium are rarely found in the stools of the healthy; in diarrheas they make their appearance. Holt and his co-workers have recorded negative balances for some of these elements, that is, losses from the body itself.

These facts are not entirely new in the domain of clinical chemistry; but they deserve emphasis here because practitioners too often fail to take them into account in their treatment. It is, as the New York pediatrists point out, not only water, but some of the inorganic salts that need to be replaced when an infant has been depleted by a severe and prolonged diarrheal attack.

RECENT METHODS FOR THE TREATMENT OF SEWAGE BY "ACTIVATED SLUDGE"

Experiments on an entirely new method of sewage treatment have been made during the past year in England, and are being continued in both England and the United States. The new process is known as the "activated sludge process" of sewage oxidation and sedimentation. Its significance may be made clear by a brief description of a typical sewage treatment plant making use of most of the advances in the art prior to the advent of the activated sludge experiments.

The city of Baltimore has constructed and is now operating in part one of the largest sewage treatment plants in the United States. Roughly, this plant includes about 6 acres of preliminary sedimentation tanks, varying from 13 to 25 feet deep; 30 acres of coarse stone sprinkling filters, about 8½ feet deep, and about 3 acres of final sedimentation tanks. The preliminary sedimentation tanks remove most of the settleable solids from the sewage, the sprinkling filters partially oxidize the remaining organic constituents of the preliminary tank effluent, and the final sedimentation tanks remove most of the oxidized settleable solids from the sprinkling filter effluent. In a general way, the object sought in the new activated sludge experiments is to do in a single set of tanks that which is now being accomplished by the sequence of preliminary tanks, oxidation-filters and final tanks. The realization of this object would mean that proposed new sewage treatment plants could eliminate the sprinkling filters and the final tanks. It would also mean that existing plants could greatly increase their present capacity for future population at a relatively low increase in cost.

The English experiments on activated sludge, and some of the proposed American investigations have been outlined in a recent publication.[1] In Manchester,

[1] Engineering Record, 1915, lxxi, 288, 521.

England, in 1913, partly at the suggestion of Dr. Gilbert J. Fowler, and partly on their own initiative, Messrs. Edward Ardern and W. T. Lockett began the series of experiments from which the new process has evolved. They found that in order to nitrify completely an average sample of Manchester sewage, it was necessary to apply continuous aeration for five weeks. Experiences similar to this had caused many investigators in the past to give up the idea of tank aeration as being much beyond the economic limit. Ardern and Lockett, however, decanting the supernatant and retaining the oxidized sludge, added a further sample of crude sewage, and continued aerating. Nitrification of this second portion occurred in a much shorter period of time. Encouraged by this discovery, the experimenters continued the accumulation of larger amounts of oxidized sludge, and finally became convinced that the presence of such accumulation of sludge deposit "had the property of enormously increasing the purification effected by the simple aeration of sewage."

Some later experiments with a cask of 50 gallons' capacity showed that by four hours' aeration the free ammonia in Manchester sewage could be reduced from 34.6 parts per million to 2.1 parts per million, and the nitrates, expressed as NH_3, increased from 0 to 16 parts per million. Subsequently, Melling and Duckworth made similar tests on a much larger outdoor scale and secured with three hours' aeration a reduction of free ammonia from 28.6 parts per million to 0.1 part per million, and an increase in nitrates + nitrites, expressed as N, from 1 part per million to 11.1 parts per million. These results are significant. Certainly the nitrification produced is ample to assure a thoroughly stable effluent.

This work, however, has all been on what is known as the "fill and draw" method of tank treatment, and the fill and draw method, as applied to the activated sludge process, consumes a large amount of hydraulic head, produces a low operation efficiency because it is an intermittent process and also necessitates periods of nonoxidation which possibly reduce the efficiency of the activated sludge. The importance, therefore, of translating the activated sludge process from the fill and draw to the continuous flow method, and of bringing the cost of operation, by this and other improvements, into the region of workable values, is obvious.

The "continuous flow" problem is the one on which attention seems to be most sharply focused at present in the current English and American experiments. In the United States, the Public Health Service is conducting, jointly with the Baltimore Sewerage Commission, experiments involving primarily a continuous flow type of tank. It is understood, also, that the Milwaukee Sewerage Commission is devoting some effort in this direction. The most important result which will be determined by these experiments is, of course, the matter of annual cost per unit of population or per unit of sewage flow. This item will eventually decide whether the activated sludge process is to replace or to eliminate oxidation filters from the modern sewage treatment plant.

The problem of the treatment of sewage of growing communities, especially of those cities located on water courses used as a source of water supply, is one of vital importance to the public health. The great decrease in the cost of construction under the new system is so large that it is quite possible that without an increase in cost over the old methods, it may be found feasible by disinfection methods to render safe the final effluent for discharge into water courses.

WILLIAM WITHERING AND DIGITALIS

In a recent appreciation of the work of William Withering, Cushny[1] describes the way in which Withering introduced the scientific use of digitalis to the medical profession. In 1741, Withering was born in Shropshire, England; in 1762 he entered the University of Edinburgh, and graduated in 1766. He began practice at once in Stafford, became attracted to botany, and in 1776 published a "British Botany." In 1778 he published an article on scarlatina anginosa, and in 1785 a book which Cushny believes entitles Withering to lasting fame. The book is entitled "An Account of the Fox Glove and Some of Its Medical Uses; with Practical Remarks on Dropsy and Other Diseases." Previous to this period, digitalis is occasionally mentioned in medical literature, for example, as an external application in scrofula, and internally in phthisis. Since the time of publication of Withering's book, its action in dropsy and on the heart has been generally recognized.

Withering states that his attention was drawn to digitalis in 1775 by its use as an ingredient of a complex cure for dropsy. He accordingly prescribed it in his dispensary, at first as a decoction of the leaves, later as an infusion, and on some occasions as a powder. The doses prescribed were large, but they proved a sovereign remedy in the cases of dropsy which he reports. Its use quickly spread.

After ten years' trial of this new remedy, Withering published an account of his work. "The deliberation with which the discovery was brought before the world," according to Cushny, "gives a delightful impression of the easy life of the eighteenth century. Now we find a new remedy exploited after an experience of months," he says, "sometimes only of weeks. Perhaps a return to the old and more cautious method is too much to wish for, but I doubt if therapeutics would suffer from it."

---

[1] Cushny, A. R.: William Withering, M.D., F.R.S., Proc. Royal Soc. Med., 1915, viii, p. 85 of section on history of medicine.

Withering's book contains reports of 163 cases, in which he had prescribed the remedy himself, and a number of others in which his friends had used it at his suggestion. He used digitalis only as a diuretic, but seemed to realize that it acted on the heart, for he affirms that "it has power over the motion of the heart to a degree yet unobserved in any medicine, and that its power may be converted to salutary ends."

Withering began to have threatenings of pulmonary tuberculosis about 1780. In 1792 he tried the effect of a warm climate, spending the winter at Lisbon. He was not favorably impressed, however, with this place as a resort for tuberculosis. He states very strongly that "phthisis is infectious." Later he remained at his home during the winters, where he kept his library at a constant temperature of 65 F. by means of flues; the windows were double sashed, and every movement was avoided as far as possible. "This treatment," says Cushny, "is an interesting contrast to the open-air method of today." Osler, discussing these points, believes that the treatment was likely "not inappropriate for a patient in the third stage of tuberculosis."

Withering died in 1799, and was buried in the old church at his home at Edgbaston, which contains a monument inscribed with his name and encircled with Witheringia, and with the purple foxglove, the plants of which he wrote. He was a man of many interests: a chemist, a botanist and an antiquarian, but above all, a physician.

THE NATURE OF BACTERIA—AN EARLY AMERICAN VIEW

For many years in the earlier history of bacteriology the micro-organisms which are its subject-matter were claimed for both the animal and vegetable kingdoms by the workers in the different domains of science. To Ehrenberg,[1] the pioneer student of bacteria, who knew little else to do with them except to classify them, they were animalcules, "devoid of an intestine and without external organs." The power of movement with which many of these minute forms were endowed placed them outside of the possibility of a plant nature to the early observers. It was the more careful study of the lower fungi that first drew attention to the similarity between bacteria and these plant forms.

The current accounts of the development of our knowledge of the bacteria state that, with the possible exception of Dujardin, all observers up to 1852 had looked on bacteria as belonging to the animal kingdom. In that year Perty announced that of these minute organisms, some belong to the animal and some to the vegetable kingdom, while a certain number appeared to him to stand on the borderland between the two. It was, above all, the eminent botanist Ferdinand Cohn who, in 1854, insisted on the plant nature of these micro-organisms. He remarked that the individuals grow and divide like plant cells; that they agree with these in structure, and particularly in the manner of fruit-forming; and that they pass through a series of intermediate steps into a higher class — that of the colorless algae. The studies of Naegeli as early as 1857 pointed in the same direction. In 1859 Davaine[2] also suggested the vegetal nature of the vibrio.

It has lately been asserted[3] that priority in the matter of identifying micro-organisms as plant forms really belongs to a well-known American biologist, Joseph Leidy, who is today remembered in particular for his notable contributions to the science of paleontology. In a paper which he presented to the Philadelphia Academy of Natural Sciences in October, 1849, Leidy remarks how, on considering that the conditions essential to vegetable growth are the same as those indispensable to animal life, he felt convinced that entophyta would be found in healthy living animals as well as, and probably as frequently as entozoa. Then follows the description of "two species of vibrio" detected by him in the alimentary tract of animals. "Even these moving filamentary bodies belonging to the genus Vibrio," says Leidy, "are of the character of algous vegetation. Their movement is no objection to that opinion, for much higher confervae, as the Oscillatorias, are endowed with inherent power of movement, not very unlike that of the vibrio."

Wherever the borderline between animal and plant forms may be placed in the future, these pioneer observations and the conclusions of Leidy respecting the place of what we now regard as bacteria among the diverse groups of living things deserve to be recognized and placed on record.

Current Comment

THE BRITISH MEDICAL ASSOCIATION WINS

The case of Stevens *vs.* the British Medical Association has been decided finally in favor of the Association. As will be remembered,[4] C. H. Stevens put on the market under various names ("Sacco," "Stevens' Consumption Cure," "Lungsava") a fraudulently exploited "consumption cure" containing a hypothetic African herb "umckaloabo." The British Medical Association, in its work of giving the public facts regarding fraudulently exploited nostrums, exposed Stevens' preparation and charged him with being a swindler and a quack who had foisted on the public a worthless remedy. This was in 1909. Stevens brought action for libel against the British Medical Association, which defended its observations on the claim that they were fair comment on a matter of public interest. At the first hearing of the case in 1912, the jury failed to agree; at the second hearing in 1914, the jury declared that the words were not libelous, that the comments were fair and it returned a verdict in favor of the British Medical Association. Stevens appealed the case and the appeal was heard on May 5, 6, and 7, 1915, with the result that Stevens lost. In his appeal, Stevens attempted to make much of the personal attack on him by the British Medical Association, but one of the judges before whom the appeal was taken, pointed out that "a comment may be fair, although it contains a personal attack." The rule as to fair comment in such cases, it was pointed out by the judge, had been clearly stated in the classic case of Dakhyl *vs.* Labouchere:

---

[1] Ehrenberg: Die Infusionsthierchen als volkommene Organismen, Leipzig, 1833.

[2] Davaine: Compt. rend. Acad. d. sc., 1859, p. 58; also Traité des Entozoaires, Paris, 1860.

[3] Leidy, Jr., J.: Morphology of the Bacteria (Vibrio and Spirillum), and Early Research, Science, 1914, xl, 302.

[4] The Journal A. M. A., Sept. 3, 1910; April 5, 1913, and Sept. 12, 1914.

> "A personal attack may form part of a fair comment upon given facts truly stated, if it be warranted by those facts. . . ."

The judge further pointed out that the courts had made it plain that "the defendant may go very far in imputing motives." One other of the three judges before whom the appeal was heard, stated that whatever was in Stevens' medicine the evidence indicated that it was, to all intents and purposes, valueless. The judge concluded that it was most important "that the right to comment should be freely exercised in cases such as this, where large sums were made out of proprietary medicines." In view of the fact that the investigations by the British Medical Association have been upheld by the courts and the fraudulence and general worthlessness of Stevens' nostrum have become a matter of record the following item that appeared in an Albany (N. Y.) paper last October is of interest:

> "'To acquire the secret process for manufacturing a remedy for tuberculosis and other diseases, discovered by Charles H. Stevens of London,' the Umckaloabo Chemical Company of New York City was incorporated with the secretary of state yesterday. The capital of the concern is $250,000. The incorporators are Samuel S. Ryckman, Edward A. Sprong and Irene V. Russell, all of New York City."

EARLY HISTORY OF TYPHUS FEVER AND PEDICULOSIS

A recent paper by Dr. Fischer[1] of Vienna gives the early history of typhus in relation to the "lice plague," now so formidable in eastern Europe. The routine history of typhus, its description by Fracastorius (1533) and as "tabardillo" by Francesco Bravo (1570), the superb account of Pringle (1752), the attempts to differentiate it from typhoid by Willis (1643), Huxham (1737), Hildenbrand (1810) and others, the final and classical differentiation by W. W. Gerhard in America (1837) and Sir William Jenner in England (1849), and the subsequent developments up to the time of Plotz are well known. Dr. Fischer lists the many curious names given to the disease during the sixteenth, seventeenth and eighteenth centuries — febris petechialis, febris maligna, febris hungarica, lues hungarica, lues pannonica, morbus castrensis and others — and states that the first description of pediculosis as a concomitant of typhus was given in a series of observations on Hungarian camp diseases, published by Tobias Cober[2] of Görlitz in 1606, and reissued by the anatomist Meibom in 1685. Under the category "*languor pannonicus*," Cober describes a group of syndromes which he regards as prodromes of typhus, but which, Fischer thinks, have nothing to do with the disease. Lice, however, Cober signalizes as a constant plague of camps, not to be prevented by careful change of clothing, as he testifies from personal experience, and producing marked psychic unrest which, with such other etiologic factors as an unhealthy climate and atmosphere, impure drinking water and irregular mode of life, might easily bring about the languor pannonicus and even the "Hungarian disease" or typhus. In his chapter "De languore pannonica, ex variis animi pathematis," Cober sets forth that mental excitement furnishes the soil for the seed, and that war itself, with its experiences of camping on the hard ground, enduring extremes of heat and cold, torrents of rain and swarms of insects, is particularly liable to bring about such excitation of spirit. Among the insect pests of war time he specifies "culices" or mosquitoes and "pediculi." A translation of his quaint description of the latter nuisance follows:

> With these foregather the most terrible pediculi, hardly to be thought of without a sense of discomfort, which in themselves, through their constant promenading and sucking of the body, are enough to stir up one's bile. For it is impossible to avoid the bites of these miserable creatures, especially in the first years in the field, as they enjoy a sort of right of citizenship in all camps. The atmosphere is so lukewarm, mild and stuffy that when clothes which have been washed in swamp water are exposed to the sunlight, they are seen to swarm with these "vermibus Syllanis." One cannot hope therefore to get away from these constant attendants and companions, as they seem to arise from the very moisture of the body itself. At first I thought to rid myself of the pest by constant change of newly washed clothing, but even this seemed to bring them more and more into play, instead of destroying them. And this phthiriasis, which even the Egyptian magi of old could not produce, but which in these localities every one can create in his own person, can, as I bear witness, drive a man into fury. For as often as I was bitten by these miserable, abject animalcules, I gave full rein to my anger, fairly gnashing my teeth with rage, and cannot even now think of them without vexation. . . . One cannot ward off these armed six-footed Turks even with iron and steel. . . . And among many soldiers I have noted the frightful spectacle that this fearful plague of lice had gone far enough to cover the whole nape with ulcers, the flesh not only excoriated to the breadth of one or two fingers, but actually excavated, the men condemned to this miserable fate dying with groans and lamentations.

SKULL FRACTURES AND "DRUNKS"

The ordinary "drunk," found on the street in a comatose condition, is thrown into a patrol wagon, allowed to achieve sobriety on the hard planks of a "lockup" bed, and usually gets but little pity on his appearance before the police court judge. The victim of a not too evident skull fracture who is found semiconscious and refused admission to several hospitals because of a hasty diagnosis of alcoholism, often — to use a well-known bull — wakes up dead in his police cell in the morning. The small town or village where the "town drunkard" forms an object lesson to all the growing youngsters is, of course, little concerned with this problem. In large cities where from two to ten such cases may occur in a single day the problem is an important one. In Chicago recently, a woman was struck by a street car, and taken at once to a local hospital. The receiving physician, acting on the hospital's rule against alcoholics, refused her admission because there was evidence that she had been drinking. The patient was then carried several miles to a police cell and a day later, following the appearance of severe symptoms, to a police hospital, in which she died. The postmortem showed the presence of a skull fracture. The coroner's jury which considered the case recommended the installation of an observation ward in the hospital where physicians might carefully examine, with roentgenography and other methods, all cases of the character described. The need of such facilities is obvious from a simple relation of the facts in this single case. Such an observation ward should not be considered a refinement of science but an absolute necessity for the saving of lives.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Personal.—Dr. Francis H. Mead, health officer of San Diego for eight years, has resigned, and has been succeeded by Dr. A. E. Banks, assistant health officer.——Dr. Hilo S. Musante, chairman of the public health board of the Civic League of Improvement Clubs of San Francisco, has resigned.

Hospital Notes.—A building is to be erected on Castelar Street, Los Angeles, by the Parent-Teacher Association for use as a free clinic for public school children.——The contract for the first three buildings of the new State Hospital at Norwalk has been awarded to a San Francisco firm for $115,000. The buildings to be erected are a two-story structure, 200 by 60 feet, for general hospital purposes; a one and one-half story building, 260 by 50 feet for both kitchen and dormitory purposes, and a one-story power house, 110 by 60 feet.——The McNutt Hospital, San Francisco, has been acquired by a syndicate of San Francisco physicians and has been renamed the Fairmont Hospital.

New Appointments on Faculty.—The following appointments to the faculty of the University of California have recently been announced: I. C. Hall, formerly connected with the Cutter Laboratories, assistant professor of bacteriology.——Dr. George W. Corner of Johns Hopkins University, assistant professor of anatomy.——Dr. Ruby Cunningham, instructor in hygiene and an infirmary physician in the infirmary of the University.——Dr. Abel W. Johnson, instructor in laryngology, otology and rhinology; Dr. Olga Louise Bridgman, Berkeley, instructor in pediatrics and mental abnormalities of childhood and Drs. Alfred E. Meyers, Howard E. Ruggles and Vivia Belle Appleton, instructors in pediatrics.

Research Associateship in Pathology Endowed.—In memory of Dr. Edith J. Claypole, Research Associate in the Department of Pathology of the University of California, who died on March 26, 1915, friends of the University have offered an annual gift of $1,200 to maintain the position of Research Associate in Pathology in the University of California, and have made definite provision for an endowment sufficient to yield this income in perpetuity. The immediate purpose of the position is to be a continuance of investigations in which much valuable work had already been accomplished by Dr. Claypole, in collaboration with Dr. Frederick P. Gay, Berkeley, Professor of Pathology in the University of California, in regard to improved methods for immunization against typhoid and methods for the treatment of that disease.

FLORIDA

Laboratory Building Finished.—The new laboratory of the State Board of Health at Pensacola, erected at a cost of $20,000, is now completed and ready for work.

Health Activities.—A vigorous campaign for a better milk ordinance is now being carried on in Pensacola.——The fight against the fly and mosquito is also in active progress.

Personal.—Dr. Fritz A. Brink, bacteriologist of the State Board of Health laboratory, Pensacola, is taking a vacation in South Dakota.——Dr. James R. Bean, Jacksonville, of the Jacksonville laboratory will take Dr. Brink's place until he returns.

Hospital Notes.—A building for tuberculosis patients has been completed at the Miami County farm. The building is 40 feet square and has been erected at a cost of $1,050.——Rapid progress is being made on the construction of the Pensacola Hospital, which when completed, will cost $400,000. It is expected that it will be ready for occupancy in September.——Articles of incorporation have been filed for the De Land Sanatorium by Frank R. Osborne and others. The institution is to have a capital stock of $50,000. Its object is to maintain a sanatorium in or near De Land and it has stated specifically that it is a corporation not for profit.——The State School for the Deaf and Blind is to have a hospital building to cost $10,000, which appropriation was made by the last legislature.——A plea for a new modern city hospital for Miami was made to the city council by Dr. John L. North, city physician. About $16,000 is at present available for this purpose, but $30,000 is required for the construction of the building.——Contracts have been let to a Tampa firm for the erection of the West Coast Hospital, Clearwater.

ILLINOIS

Hospital Incorporated.—The Evangelical Hospital and Deaconess Association of Southern Illinois which has charge of the Henrietta Hospital, East St. Louis, filed incorporation papers May 24.

Victory in House for University.—On June 2, the House of Representatives passed a bill appropriating $5,000,000 for the University of Illinois, a portion of which, about $100,000 will it is said, be utilized for the purchase of ground for the medical school and hospital of the university.

Highland Park Leper Returns to Italy.—Angelo Lunardi, the Highland Park leper whose name has been so prominently before the public for several months, is said to have been secretly deported to his home in Italy. He was taken to New York by his friends and put aboard a steamer for Italy which sailed June 3.

Chicago

Summer Hospital Will Soon Open.—The *Tribune* Summer Hospital for the Convalescent at Algonquin, with accommodations for from six to seven hundred sick women and their babies, will be opened for the season June 21.

Physicians Club Election.—At the annual meeting of the Physicians Club at Chicago, held June 3, the following directors were elected: Drs. Henry T. Byford, Joseph Zeisler, and Charles P. Caldwell; and Dr. Arthur M. Corwin was elected secretary.

Northwestern Alumni Election.—At the annual meeting of the Alumni Association of Northwestern University Medical School, held June 7, the following officers were elected: president, Dr. William R. Cubbins, '00; secretary, Dr. Arthur B. Eustace, '07 (reelected); treasurer, Dr. Leo G. Dwan, '07 (reelected); and necrologist and Alumni editor, Dr. Samuel C. Stanton, '92. At the alumni banquet that followed the meeting, Dr. Archibald Church presided as toastmaster and the speaker of the evening was Prof. E. R. Keedy who delivered an address on "Medico-Legal Criminal Borderland."

To Fight Rabies.—At a meeting called bv Alderman Willis O. Nance, chairman of the Council Committee on Health, June 4, plans were discussed for the limitation of rabies which has increased so materially in the city of late. At the conference were present the health commissioner, chief of police, superintendent of the dog pound, coroner, a representative of the Chicago Kennel Club, Aldermen Hugo Krause and Oliver B. Watson, and Drs. James A. Clark, Frederick A. Fisher, James E. Stubbs and William A. Evans. It was suggested that an all the year muzzling law would prove effective, but no definite action was taken.

Chicago Unit for War Service Ready.—The Chicago unit leaves by the New York Central line from La Salle Street Station, Sunday, June 13, at 11:30 p. m. The unit will sail on the steamship *New Amsterdam* of the Holland American Line, Tuesday, June 15, at noon, from Hoboken, N. J., and land at Falmouth, England. The purpose of the organization is to take charge of a base hospital of 1,040 beds in England or field work on the continent. The personnel of the unit is as follows: Drs. James M. Neff, Operating Surgeon, Spokane, Wash.; Geo. G. Davis, Operating Surgeon, Chicago; W. E. Leighton, Operating Surgeon, St. Louis; Philip S. Chancellor, Medical Consultant, Chicago; Geo. P. Gill, Associate Surgeon, Rockford, Ill.; W. R. Rainey, Associate Surgeon, Salem, Ill.; Waldo Richardson, Associate Surgeon, Seattle; Ralph L. Thompson, Pathologist, St. Louis; Edward M. Auer, Neurologist, Skillman, N. J.; Geo. E. Meyer, Oral Surgeon, Chicago; Chas. Maghy, Ophthalmologist, Chicago; W. Earl Ball, Roentgenologist, Chicago; Scurry Terrell, Ear, Nose and Throat Surgeon, Dallas, Tex.; J. F. Archibald, Associate Pathologist, St. Louis; John G. O'Malley, Chicago, Surgeon and Secretary; D. F. Hayes, Chicago; R. B. Haven, Chicago; R. B. Acker, Chicago; P. M. Dale, Chicago; S. Walker, Chicago; E. L. Cavanee, Chicago; E. Lee, Seattle; R. D. Long, Oklahoma City; C. D. McLean, Oklahoma City; C. Smith, Kalispell, Mont.; W. G. Uppendahl, Peoria, Ill.; J. S. Fox, Silverton, Colo.; J. J. Hilton, Chicago; C. R. Stanley, Indianapolis; J. R. Taylor, Madison, Wis.; A. H. Hixson, Columbus, Ohio; Fred Moeller, Chicago; Fred S. Jacobs, Chicago.

Dr. James Neff and Dr. Chancellor sailed June 2, on the steamship *Rotterdam* to make preliminary arrangements.

Seventy nurses, most of them graduates of local training schools, will also serve with this unit.

INDIANA

Tuberculosis Survey to Be Made.—Surg. James C. Perry, U. S. P. H. S., arrived in Richmond, May 27, to conduct a tuberculosis survey in the city.

Health Officers Oppose Alcohol.—At the annual conference of the health officers of the state, held at Indianapolis, May 12, about 200 health officers were in attendance, and Dr. George W. Bence, Greencastle, was chairman. A resolution was unanimously adopted declaring that physicians and health officers should join in the campaign against alcohol.

Personal.—Dr. L. Oilar, Indianapolis, has been commissioned as first lieutenant, M. C., Ind. N. G.——Dr. Gustavus B. Jackson has been elected president of the Indianapolis City Board of Health, succeeding Dr. T. B. Victor Keene, membership expired.——Dr. Eugene B. Mumford has been appointed a member of the Indianapolis Board of Health.——Dr. Boston H. B. Grayson, Huntington, who recently underwent an operation for appendicitis in the Huntington County Hospital, has returned home convalescent.——Dr. Norman F. Peacock, Darlington, is reported to be suffering from septicemia.——Dr. Clint C. Sourwine, Brazil, who has been seriously ill with septicemia, is reported to be improving.

Prosecution of Chiropractors.—The State Board of Medical Examiners has been taking up the question of the chiropractors. At Crawfordsville, Montgomery County, William A. Summerville, after being convicted once of practicing medicine without a license, attempted it again, but on being again indicted, left before he could be arrested. William N. Tyson, a masseur, at first employed under the direction of the physicians of Crawfordsville, it is said began soliciting and treating patients on his own account, using chiropractic methods. He was indicted, tried, and on May 27 fined $25 and costs in the circuit court of Montgomery County for practicing medicine without a license. He paid the fine and agreed not to repeat the offense. Mrs. Ellen Cunningham and Paul F. Myers, chiropractors, the latter a recent "graduate" of the Palmer School at Davenport, Iowa, were also charged at Crawfordsville with practicing medicine without being authorized to do so. Mrs. Cunningham is defended by Attorneys Morris & Hartwell of La Crosse, Wis., a firm frequently employed to defend chiropractors in various states, it is said, in the interest of certain chiropractic schools. A motion to quash the charges in the case of Mrs. Cunningham reveals the general grounds on which the chiropractors seek to defeat the provisions of the medical practice acts where chiropractors are haled into court for illegally practicing medicine. It is declared that the court has no jurisdiction; that the Indiana practice act is not in accord with the national Constitution; that it impairs the obligation of contracts and violates the constitutional provision that all shall have equal rights in the several states; that a speedy trial is not provided for; that the law is arbitrary and attempts to give exclusive rights to some, and to show how knowledge of medicine or surgery shall be obtained, is class legislation, has been enacted for private gain, attempts to settle questions of science, declares that practice of medicine and surgery which is not such practice, and imposes unnecessary restrictions and is not a proper exercise of the police powers of the state. It is also declared that the law violates the constitution of Indiana, and that the charge against Mrs. Cunningham embraces two offenses while only one is specified in the title. The case was to have come to trial the last week in May, but a continuance was asked by the defendant. The case of Myers has not yet been reached.

IOWA

Eastern Surgeons Visit Iowa.—Dr. George W. Crile, Cleveland, delivered an address before a joint meeting of the Scott County and the Rock Island County (Ill.) medical societies in Davenport, June 8.——Dr. George L. de Schweinitz, Philadelphia, was the guest of honor at a luncheon in Iowa City, May 13, which was given by eye, ear, nose and throat specialists of the city.

Tuberculosis Sanatoriums.—At a meeting of the Pottawattamie County Medical Society held in Council Bluffs recently, formal endorsement was given to the proposed sanatorium for the treatment of tuberculosis and the proposition of a tent colony near McClelland was favored.——The Woodward County Board of Supervisors has contracted for the erection of a modern tuberculosis hospital in Sawyers Bluff, Sioux City, at a cost of from $12,000 to $15,000.

Kepford Resigns.—Aretas E. Kepford, for nine years state lecturer on tuberculosis, has resigned to take effect July 1, and will enter evangelistic work. During Mr. Kepford's nine years of service he has seen a decrease in the mortality from tuberculosis in the state of almost 40 per cent., has traveled several thousand miles and has delivered more than 2,000 lectures to more than half a million people, and by his efforts has greatly assisted in the establishment of the State Sanatorium, Oakdale.

Personal.—Dr. William H. Newlon, Fort Madison, has started for the Pacific Coast.——Dr. Otto J. Yelt, Colfax, sailed from New York, June 1, for service with the French army.——Dr. Albert Anderson, Estherville, was operated on, May 13, for appendicitis and cholelithiasis, and is reported to be doing well.——Dr. Floyd S. Clarke, Lemars, has moved to New York City.——It is announced that Dr. Max W. Emmert will leave Atlantic City, N. J., some time this month and will locate in Des Moines.

State Society Meeting.—The sixty-fourth annual meeting of the Iowa State Medical Society was held in Waterloo, May 12 to 14, under the presidency of Dr. Henry C. Eschbach, Albia, and the following officers were elected: president-elect, Dr. John F Harrick, Ottumwa; president, Dr. William B. Small, Waterloo; vice presidents, Drs. John E. Luckey, Vinton, and Harvey B. Gratiot, Dubuque; secretary, Dr. James W. Osborn, Des Moines (reelected); treasurer, Dr. Thomas F. Duhigg, Des Moines; councilors, first district, Dr. John R. Walker, Fort Madison, and eleventh district, Dr. Giles C. Moorehead, Idagrove; delegate to the American Medical Association, Dr. John C. Rockafellow, Des Moines; and alternate, Dr. Frank M. Tombaugh, Burlington. Davenport was selected as the place of meeting for 1916.

KENTUCKY

Hospital News.—The Clark County Fiscal Court on May 12 agreed to give $5,000 toward the proposed hospital at Winchester provided that a subscription of $25,000 is secured.——The city council of Henderson has passed an ordinance appropriating $25,000 for the establishment of a hospital in that city.

Personal.—Dr. J. Morrison Ray has been appointed a member of the board of trustees of the Louisville Public Library, succeeding Dr. Chester A. Mayer, deceased.——Dr. R. Julian Estill, Lexington, who has been seriously ill at the Good Samaritan Hospital in that city for six weeks, is reported to be convalescent.——Dr. U. V. Williams, Frankfort, has been reappointed a member of the state tuberculosis commission.——Dr. Leon L. Solomon has been elected dean; Dr. Frank W. Fleischaker, vice dean, and Dr. Siegel C. Frankel, secretary, of the staff of the Jewish Hospital, Louisville.——Dr. Frank Fithian, Paris, is reported to be seriously ill with rheumatism in Martinsville, Ind.——Dr. W. Hamilton Lond, Louisville, has been elected president of the Interstate Association of Anesthetists.——Dr. Thomas L. Harris has succeeded Dr. James Cruce as chief resident physician at the Louisville City Hospital.——Dr. Simeon K. Fisher, Milton, is reported to be seriously ill with heart disease.

MARYLAND

Public Meeting on Cancer.—As a part of the nation-wide movement against cancer, the Baltimore City Medical Society, acting jointly with the committee on public instruction of the Medical and Chirurgical Faculty of Maryland, held an interesting meeting in Osler Hall on June 4. The speakers were Dr. Jonathan M. Wainright, Philadelphia, who is chairman of the cancer committee of the Pennsylvania State Medical Society; Dr. Julius Friedenwald, Baltimore, who spoke on "What Everyone Should Know About Cancer of the Stomach," and Dr. Fred V. Beitler, Halethorp, of the State Board of Health. Dr. William H. Welch, Baltimore, presided at the meeting.

Personal.—Dr. Burns S. Chaffee, Baltimore, will become resident physician of the Union Protestant Infirmary, succeeding Dr. Edwin G. Davis, Baltimore, when changes in the hospital staff take place this summer. Dr. Davis will remain as a member of the staff. Dr. Chaffee has been connected with the institution for several years.——Interns W. S. Bean, Jr., and W. Y. Hollingsworth, interns in the United States Marine Hospital, Baltimore, have resigned and have been succeeded by Drs. M. V. Ziegler and Harry Schmuck.——Dr. William Lee Smith, Riderwood, is under treatment in Johns Hopkins Hospital, Baltimore.——Prof. Thomas L. Patterson of the University of Maryland Medical School has accepted the position of assistant professor of physiology in the medical faculty of Queen's University, Kingston, Ont.——Dr. A. Clarence Smink, Baltimore, sustained injuries of the head in a collision between the automobile in which he was riding and a street car, May 29.——Dr. Thomas S. Cullen, Baltimore, who was operated on for appendicitis and cholecystitis, May 29, is reported to be making satisfactory progress.——Dr. Alfred Whitehead, Baltimore, is under treatment in Johns Hopkins Hospital.

Medical Schools Merge.—A plan to merge the University of Maryland Medical School and the College of Physicians and Surgeons, which has been under way for months, has been consummated. The merger applies only to the work of the first two years. The third and fourth year classes will continue to be taught separately by the two respective faculties. The combined school will receive from the regents of the Maryland State University $15,000 for each of the years 1915 and 1916. An act of the legislature, which created the Maryland State University, gave that institution the sum named to be used for medical education in the state. Neither of the schools now receives state aid. The University of Maryland regents will be increased to include eight men as representatives of the College of Physicians and Surgeons; and the medical faculty of the university will be increased by ten from the physicians and surgeons, making twenty-one in all. There will be no resignations. The University of Maryland Medical School was established in 1807 and the College of Physicians and Surgeons in 1872. Dr. Arthur M. Shipley is dean of the former and Dr. William F. Lockwood is dean of the latter institution. The University of Maryland Medical School occupies the oldest medical building in the United States, now being actively used in medical teaching.

MICHIGAN

Holmes Guest of Honor.—Dr. Arthur D. Holmes, Detroit, past president of the Wayne County Medical Society, to whose activities were largely due the success of the enterprise of securing permanent quarters for the society, was the guest of honor at a testimonial dinner given by members of the organization, May 21, at which Dr. Wadsworth Warren, Detroit, officiated as toastmaster.

Clinic Week at Medical College.—The annual clinic week in Detroit College of Medicine and Surgery began May 26. The program of this week has already appeared in The Journal, and it remains only to say that the week was a notable success.——At the annual meeting of the Alumni Association held on the steamer *Tashmoo*, June 2, Dr. Alexander W. Blain, Detroit, was elected president; Dr. Frederick W. Robbins, Detroit, honorary president, and Dr. Charles W. Husband was reelected secretary-treasurer.

Personal.—Dr. Arthur O. Ullrey, Niles, was operated on at the Epworth Hospital, May 9, and is said to be doing well.——Dr. William J. Rynearson, Parshallville, was seriously injured, May 31, when a runaway horse collided with the automobile in which Dr. Rynearson was riding.——Dr. A. A. Spoor, Big Rapids, has been appointed assistant state bacteriologist, with headquarters at the new laboratory which the State Board of Health has decided to open at Houghton.——Dr. Louis Barth, Grand Rapids, has started on a trip to the Pacific Coast.——Dr. Felix J. Pzbylowski has won his suit against the poor commission for $1,033.33, and the judge has ordered that Dr. Pzbylowski be restored to office as city physician of Detroit.——Dr. John C. Brown, Battle Creek, has been appointed a member of the State Pardon Board, vice Dr. Karl B. Brucker, Lansing.——Dr. and Mrs. John H. Kellogg, Battle Creek, returned May 20, from a tour to the Pacific Coast.——Dr. Arthur D. Bangham, Albion, underwent an operation in Battle Creek, May 20, for the enucleation of the right eye.——Dr. Ralph G. Cook has resigned as chief of the Kalamazoo Antituberculosis Society, and is succeeded by Dr. R. Genung Leland, East Le Roy.——Dr. Ralph C. Apted, city physician of Grand Rapids, who was operated on for disease of the liver at Butterworth Hospital, May 8, is reported to be improving. Dr. Allison H. Edwards is in temporary charge of Dr. Apted's work.——Dr. Thomas J. Henry, city physician of Detroit, has recovered from the effects of an accidental dose of carbolic acid.——Dr. John T. Cooper has been appointed local surgeon for the Pere Marquette Railroad Company at Muskegon, to succeed Dr. Albertus B. Poppen.

MINNESOTA

Summer Course at University.—A course for practitioners will be given by the University of Minnesota medical department, during the entire month of July. The full summer session of the medical school will begin June 14 and end July 23. The clinics in the City Hospital, Minneapolis, will be open to graduate students and practicing physicians.

Health Survey Planned.—Dr. H. M. Bracken, secretary of the State Board of Health, announces that the board will designate one county in the state in which a thorough health survey will be conducted. Beginning on July 1, a detachment of officials from the United States Public Health Service will enter the county designated, examine every householder and make a detailed report of the sanitary condition of the premises and the occupants.

Tribute to Pioneer Surgeon.—A life-sized bronze statue of the late Dr. W. W. Mayo, presented by the people of Rochester and Olmsted County, was unveiled in Mayo Park, Rochester, May 29. Rt. Rev. Thomas O'Gorman, Sioux Falls, S. D., and former Chief Justice Charles M. Stark, two of Dr. Mayo's most intimate friends, delivered addresses during the ceremonies. On the base of the statue are carved the words:

William Worrel Mayo,
Born May 31, 1819, Died March 6, 1911.
Pioneer Physician Citizen.
A Man of Hope and Forwardlooking Mind.

Time-Limit Quarantine for Diphtheria.—The director of the division of preventive diseases of the State Board of Health has issued a circular to health officers and physicians which states that owing to the closing of the State Board of Health laboratories, May 15, a time-limit quarantine for diphtheria supersedes control by the culture method until August 1, when laboratories will resume work. Quarantine must be continued for at least three weeks after the disappearance of all clinical symptoms of diphtheria.——To facilitate the distribution of free diphtheria antitoxin, throughout the state, the secretary of the State Board of Health has designated 122 stations at which the indigent may obtain free antitoxin. The attending physician in each case must determine whether the patient is entitled to the benefit of this provision.

Personal.—Dr. Charles H. Mayo has been appointed a member of the Board of Education of Rochester.——Dr. Christian Johnson, Wilmar, who underwent operation recently in St. Paul, is making satisfactory progress toward recovery.——Dr. Thomas M. Joyce, Janesville, is reported to be ill in St. Joseph's Hospital, Mankato.——Mr. L. P. Wolf, a consulting engineer of St. Paul, has been appointed a member and consulting engineer of the State Board of Health, succeeding Dr. Charles Lyman Greene, St. Paul, resigned.——Dr. Michael Sullivan, Adrian, was operated on for hernia at Luverne Hospital, recently, and is said to be doing well.——Dr. Rudolph A. Beise has been elected mayor of Brainerd.——At the fifty-seventh birthday exercises of the state of Minnesota, held in the Old Capitol Building, St. Paul, May 11, Dr. John M. Armstrong gave a review of the lives of pioneer physicians of Minnesota.

Public Health Association Meeting.—At the annual meeting of the Minnesota Public Health Association held May 18, the following officers were elected: Governor W. S. Hammond and President George E. Vincent, honorary vice presidents; James T. Jerould, Minneapolis, vice president; Dr. W. L. Beebe, St. Cloud, secretary; Dr. Paul B. Cook, St. Paul, treasurer; Drs. Paul B. Cook, St. Paul; Halvor Holte, Crookston; and Messrs. W. A. Laidlaw, St. Paul; H. L. Merrill, Hutchinson; C. C. Stillman, St. Paul, and Mrs. A. L. Robinson, Warren, directors. The executive secretary, Dr. H. W. Hill, was granted leave of absence for seven months and at the adjourning annual meeting, May 24, Dr. Ignatius J. Murphy, Duluth, was unanimously elected secretary to act in Dr. Hill's absence, and has already entered on his duties. The association proposes a stirring public health campaign to arouse interest and secure for the next legislature advances in public health work which were refused by the last legislature. County public health associations are to be formed and an active campaign for membership is to be inaugurated.

NEW YORK

Long Island Hospital for the Insane.—Governor Whitman has signed the legislative appropriation permitting the State Hospital Commission to enter into contracts for additional quarters for patients at the Long Island State Hospital to the amount of $400,000, of which $200,000 is available at once.

Buffalo Alumni Assemble.—The fortieth annual meeting of the Alumni Association of the Medical Department of the University of Buffalo was held at that institution June 1 to 4, and the following officers were elected: president, Dr. Lesser Kaufman, '04, Buffalo; secretary, Dr. Julius Richter, '04, Buffalo, (reelected); treasurer, Dr. Frank E. Brundage, '09, Buffalo; and trustee, the retiring president, Dr. George F. Cott, '84, Buffalo. The annual alumni dinner was held on the evening of June 3, Dr. Thomas H. McKee, '98, officiating as toastmaster.

New York City

Raising Requirements for Health Inspectors.—Dr. Sigismund S. Goldwater, commissioner of health, has announced that in the future all applicants for the position of medical inspector, to which physicians only are eligible, must show at least one year of hospital experience as an intern in addition to the medical course.

Crocker Research Fund.—The trustees of Columbia University have appointed the following board of managers of the George Crocker Cancer Research Fund: Drs. T. Matlack Cheesman, and Walter Mendelson, President N. M. Butler, Dean Samuel W. Lambert, and Profs. Warfield T. Longcope, William G. MacCallum, and Francis Carter Wood.

Geriatrists Organize.—The New York Geriatric Society was organized June 2, its object being the scientific study of senile conditions, the cause of aging, the diseases of advanced life and the home and institutional care of the aged. The following officers were elected: president, Dr. Robert Abrahams; vice-president, Dr. Edward P. Swift and secretary, Dr. Ignatz L. Nascher.

Supreme Court Sustains Muzzling Law.—The Appellate Division of the Supreme Court, on March 29, 1915, unanimously sustained the validity of that section of the Sanitary Code which prohibits any unmuzzled dog on any highway or in any public park or place in the city of New York. This finally disposes of the "Knoblauch" case and upholds Justice Lehman of the Supreme Court in his opinion that the ordinance is a valid and reasonable exercise of the police power of the Board of Health.

Systematic Inspection of Farm-Killed Meat.—After a number of conferences between the department of health and the board of aldermen it was decided to inaugurate a system of inspection of farm-killed meat, to be performed by veterinarians qualified in postmortem examinations, the cost to be met by the firms selling the goods. An ordinance on these lines was drafted and sent to the board of aldermen, and was passed by that body on May 11.

Columbia's Plan Announced.—More definite plans for the new medical plant in connection with Columbia University were announced June 1. The total cost of the project will be $16,700,000 of which the share of the Presbyterian Hospital will be $9,200,000. The plans include a hospital designed to contain 650 beds and seventy-five private rooms. Provision will be made for the permanent location of the George Crocker Cancer Research Foundation, and the Vanderbilt Clinic will be rebuilt as a part of the new hospital. The plans also include a students' dormitory which will accommodate 400 students. At present the College of Physicians and Surgeons has a deficiency of about $150,000 a year. The urgently needed department of sanitation will require an additional $40,000 per year and it is pointed out that the usefulness of the medical school along many lines is hampered by lack of funds. The university must raise a total fund of $7,500,000 in order to carry out its plans.

Personal.—Dr. Matthias Nicoll, Jr., has been appointed assistant director of laboratories of the Department of Health at a salary of $3,000 per year.——Dr. Abraham L. Wolbarst was the guest of honor at a dinner given May 12, by physicians who had attended his Thursday night genito-urinary clinics at the West Side German Dispensary and Hospital during the winter. Dr. Simon C. Grudberg acted as toastmaster.——Dr. Alfred Stillman, II, sailed for Europe June 5, for duty as surgeon in Mrs. Henry Payne Whitney's Hospital in France.——Dr. William V. Pascual, Brooklyn, was operated on for appendicitis May 25, and is said to be doing well.——Dr. Lucius F. Herz was struck by an automobile in New Haven May 22, and sustained a fracture of the left leg above the knee in addition to numerous cuts and bruises.——Dr. Simon Flexner, director of medical research of the Rockefeller Institute, was given the honorary degree of LL.D. by the University of Maryland, Baltimore, May 21.

PENNSYLVANIA

Gift to Hospital.—The Benjamin A. Haywood memorial dispensary and pathological laboratories, presented to the Sibly Memorial Hospital, Washington, by Mrs. Elizabeth E. Haywood of Sheran as a memorial to her husband, were formally dedicated, May 18. The laboratories are thoroughly equipped and the dispensary will be opened for free patients daily.

Philadelphia

Woman's Medical College Commencement.—The fortieth annual commencement exercises of the Woman's Medical College of Pennsylvania, Philadelphia, were held at the college, June 2. Dr. Richard C. Cabot, professor of medicine in Harvard Medical School, delivered the doctorate address.

College Commencements.—The thirty-fifth annual commencement of the Medico-Chirurgical College of Philadelphia was held at the Academy of Music, June 4. Mr. Clinton Rodgers Woodruff delivered the address to the graduates.——The ninetieth annual commencement of Jefferson Medical College was held June 5 at the Academy of Music. There were 145 graduates. The annual address to the students was delivered by Dr. Victor C. Vaughan, Ann Arbor, Mich. His subject was "The Doctor's Ideals." The degree of LL.D. was conferred on Dr. Vaughan by the president of the board of trustees.

Alumnae Election.—The election of officers of the Alumnae Association of the Woman's Medical College of Pennsylvania, June 3, resulted as follows: president, Dr. Elizabeth L. Peck; director, Dr. Catherine Macfarlane; recording secretary, Dr. Jacobina S. Reddie; corresponding secretary, Dr. Mary Buchanan; and treasurer, Dr. Ellen C. Potter. The alumnae decided to appoint a committee of five to consider the enlistment of thirty or more volunteer women physicians to be sent to Europe to aid in the care of war babies and their mothers. Dr. Harriette L. Hartley was appointed chairman of this committee and instructed to correspond with the representatives of war powers concerning the location of a hospital in the war zone for women and children.

Jefferson Alumni Meeting.—The annual banquet of the Alumni Association of Jefferson Medical College was held June 4. Dr. Francis T. Stewart acted as toastmaster and speeches were made by Mr. Potter, president of the board of trustees; Dr. William W. Keen, professor emeritus, and Prof. J. Parson Scheffer. The announcement was made of the promise of a gift of $100,000 by one of the diners for the purpose of swelling the endowment fund, the only stipulation being the raising of an equal amount by the alumni of the institution. The name of the donor was withheld. At this time Dr. William W. Keen, emeritus professor of surgery in Jefferson Medical College, was presented with two beautiful silver platters as a token of esteem and love by the association. Dr. B. Franklin Royer, Harrisburg, was elected president for the ensuing year.

WEST VIRGINIA

New State Department of Health.—An act passed by the last legislature provided for the new organization of the Health Department and that a new Council on Health should take the place of the old board of health. The following have been appointed members of the council: Dr. Samuel L. Jepson, Wheeling, commissioner of health; and Drs. William W. Golden, Elkins, Joseph L. Pyle, Chester; Will J. Davidson, Parkersburg, and Joseph E. Robins, Charleston, who were members of the old board; and Dr. J. S. Farmsworth, Frenchton, and Wilkin B. Stephens, Kimball, new members. The Council on Health will continue to perform the function of the old board as an examining board and it is announced that the next examination will be held in Charleston, July 7.

CANADA

Personal.—Dr. Robert M. Simpson, Winnipeg, chairman of the Board of Health of Manitoba, is to go to the front and take charge of a large hospital.

Hospital News.—Temporary accommodation has been provided for 100 children of the Children's Hospital, Toronto, on Toronto Island, the summer home at that point having been destroyed by fire in April. Several portable sheet steel buildings, including a dispensary have been provided.——The Canadian Militia Department have decided to accept the offer of Laval University, Montreal, for a hospital of 1,000 beds for service in England or France.——On the first day the lists were opened for the Ontario Government Hospital to be established in England, there were 100 applications from medical men. Fifty physicians and surgeons are required.

GENERAL

State-District Medical Society Meets.—The annual meeting of the Medical Society of Northern Virginia and the District of Columbia was held, May 19, in Alexandria, Va., and the following officers were elected: president, Dr. Samuel B. Moore, Alexandria, Va.; vice presidents, Drs. John B. Nichols, Washington; and George R. Cottingham, Remington, Va.; recording secretary, Dr. Thomas A. Groover, Washington; corresponding secretary, Dr. Joseph D. Rogers, Washington; and treasurer, Dr. William I. Robey, Herndon, Va.

Bequests and Donations.—The following bequests and donations have recently been announced:

Federation of Jewish Institutions, Philadelphia, $1,000, by the will of Dr. Henry Van Beil.

Up to May 28, the campaign fund for the Sisters of Mercy fund, West Philadelphia, had reached $122,048.22.

Henry A. Rexler Orphans' Home, Allentown, Pa., $60,000, by the will of Henry A. Rexler.

Jewish Hospital, Philadelphia, $2,000, for the endowment of the Leffman and Rosalie L. Hope bed, by the will of Rosalie L. Hope.

St. Joseph's Hospital, Philadelphia, $2,500, by the will of Annie Campbell.

Medical Jurisprudence Society Meets.—The third annual meeting of the American Association of Medical Jurisprudence was held at Hotel Trownvill, Long Beach, L. I., under the presidency of Mr. Charles A. Boston, New York, and the following officers were elected: president, Dr. D. Percy Hickling, Washington, D. C.; vice presidents, Mr. Oscar W. Earhorn, New York City, and Dr. Philip Coombs Knapp, Boston; secretary, Mr. Charles P. Blaney, New York City (reelected); treasurer, John Castree West, New York City; and councilors, Drs. Frank H. Daniels, Frank W. Robertson and A. Ernest Gallant, New York City; Donald D. MacTaggart, Montreal, and Reynold Webb Wilcox, New York City; and Messrs. John S. Durand, Alfred E. Ommen, Theodore Sutro, Harold Hirsch and Harry V. Osborne.

Cancer in Vermont.—The New England states have been much aroused recently on account of the higher death rate from malignant diseases, which has been reported by census statistics to prevail. The general mortality rate from cancer in the United States is 78.9 per 100,000 population. In the New England states the lowest rate was 85.1 per 100,000. Rhode Island's rate was 93.3; that of Massachusetts, 101.4; that of New Hampshire, 104.4; that of Maine, 107.5, while Vermont heads the list with 111.7 deaths per 100,000 of population. Vermont was so aroused by the publication of these statistics that the State Medical Society arranged for meetings and lectures in Rutland, Burlington, Montpelier and St. Johnsbury to start a campaign of education. These meetings were held June 8 to 11. The afternoon sessions were for the medical profession, while in the evenings the general public was invited.

FOREIGN

Deaths in the Profession Abroad.—Haltenhoff, formerly professor of ophthalmology at Bern, aged 73.——Frankenberger, professor of otology at the Bohemian University of Prague.

Our Foreign Exchanges.—The August, 1914, number of the *Journal de Chirurgie* has reached us, published in April, 1915, and the four other numbers for 1914 are promised before the end of 1915. This issue contains long summaries, some illustrated, of numerous articles in The Journal and other American publications. As is evident from our Foreign Current Literature Department, the German exchanges, all the weeklies and the high grade *Archivs* and *Zeitschrifts*, have never suspended publication, and except that their contents are devoted mostly to military surgery and hygiene, there is nothing in their aspect or make-up to suggest that their country is at war.——The *Zeitschrift für Geburtshülfe und Gynäkologie* has just been received, the first since early in the spring. This *Zeitschrift* is one of the journals issued irregularly, only as material accumulates. This number bears a mourning border on account of the death of its editor in chief, Prof. R. Olshausen a few months ago.

Chair of Tropical Diseases in Italy.—Naples was selected as the best location for the newly founded university professorship of tropical diseases, and A. Castellani has been placed in charge. Since 1903 he has been chief of the clinic for tropical diseases on the island of Ceylon, a British institution, after having worked long with Sir Patrick Manson at London. Castellani was sent to Uganda in 1901 to 1903 by the British authorities and his work there was crowned by the discovery of the causal agent of sleeping sickness. The *Riforma Medica* of Naples states that he has described about thirty new forms of tropical diseases, including endemic funiculitis and forty new species of pathogenic bacteria, such as that of Ceylon paracholera, besides several protozoa. He has also contributed much to improve bacteriologic technic and methods of vaccination.

WAR NOTES

Typhus Checked.—Reports were received by the state department in Washington, June 3, that the campaign against typhus in Serbia is going steadily forward and that the disease is being rapidly suppressed.

Training Official Disinfectors.—The state authorities in Germany have ordered all communities to make arrangements for a trained corps of disinfectors in readiness for an invasion of typhus. The training must include instruction in vermin extermination. The three-day courses are to be taken in some state disinfection training school.

Red Cross Notes.—The American Red Cross reports under date of June 5, that there were 10,000 wounded soldiers in Constantinople as long ago as May 8, and that more were arriving daily. The two Red Cross hospitals in Constantinople are absolutely filled with wounded soldiers and many of the colleges and Greek schools have been taken over by the authorities and converted into hospitals.——The Beirut, Syria, chapter of the American Red Cross has equipped a field hospital which is actively at work.

Aid for Belgian Physicians.—The report of the treasurer of the committee of American physicians for the aid of the Belgian profession, for the week ending June 5, 1915, lists the following contributions:

Dr. Arthur G. Larkin, New York, N. Y.	$ 10.00
Dr. John A. Hawkins, Pittsburgh, Pa.	10.00

Medical Society of the Co. of Greene, Catskill, N. Y.		15.00
Wilson County Medical Society, Fredonia, Kans.		15.00
Dr. Robert C. Davis, Johnstown, Pa.		5.00
Dr. Emery Marvel, Atlantic City, N. J.		25.00
Dr. G. J. Hagens Chicago, Ill.		15.00
Medical Society of the County of Westchester, White Plains, N. Y. (second contribution)		2.50
Rockland County Medical Society, Nyack, N. Y.		28.00
San Luis Valley Medical Society, Alamosa, Colo.		25.00
Receipts for the week ending June 5		$ 150.50
Previously reported receipts		7,008.50
Total receipts		$7,159.00
Previously reported disbursements:		
1,625 standard boxes of food at $2.20	$3,575.00	
1,274 standard boxes of food at 2.30	2,930.00	
213 standard boxes of food at 2.28	485.64	
Total disbursements		6,990.84
Balance		$ 168.16

F. F. Simpson, M.D., Treasurer,
5 Jenkins Arcade Bldg. Pittsburgh, Pa.

FROM SIR WILLIAM OSLER

Oxford, May 26, 1915.

Medical Notes on England at War

FUNCTIONAL NERVOUS DISORDERS

Types rarely seen in males in this country or in the United States are very common, and an explanation is to be found in the extraordinary stress and strain of the trench fighting.

Shell-Shock Paraplegia.—Without actual injury, the close proximity of the explosion causes loss of consciousness or a dazed condition which lasts for some hours or longer, with a paraplegia persisting for days or even for weeks and gradually disappearing. In the cases which I have seen, the reflexes have been present or have been increased. In one there was hypertonus of the muscles; sometimes there have been hyperesthesia and transient difficulty with the bladder and bowels. In severe cases following partial burial by the explosion, even without bruising, there may be hemorrhage and a much more serious type of paraplegia, with the legs completely flaccid and abolition of the reflexes.

Psychic "Knock-Out."—This condition, due to shell shock, is a remarkable one in which the victim remains in a state of stupor, with loss of memory and complete speechlessness or stammering, recovery following in a few days; but a condition of nervous irritability may persist for weeks.

Involvement of the Special Senses.—This is common. One man near whom a shell had exploded, but who was not struck by any fragments, had headache and a blinking tic, a constant quivering blepharospasm, so that he could not open his eyes; the conjunctivae and media were clear and there were no retinal changes. He kept the head depressed, and the photophobia was extreme, but he gradually recovered. A very puzzling case which interested us greatly at Clevedon was a man with monocular amblyopia, without visible changes in the fundus or in the reflexes; there was in the left eye complete defect of vision, except a very small area in the temporal field. Mr. Lawford, ophthalmic surgeon to the St. Thomas Hospital, who made a careful examination, concluded it was a functional defect. I see that Dr. Turner mentions a somewhat similar monocular case with ptosis.

Functional Dysbasia.—All sorts of anomalous gaits are encountered. One of the most remarkable was a tight rope walker's type in a functional dysbasia following shell shock. The subject, an intelligent young officer, wrote down the following statement about the accident:

> "The Germans had been shelling our dummy trenches, which were about 20 yards to the rear of the trench in which I was. The oncoming shells give just enough warning to allow one to lean against the front wall of the trench—the position of least danger from shell fire. I heard my particular shell coming, and from force of habit leaned toward the front wall and looked toward the rear dummy trench to see the shell burst as the others had done. Suddenly there was a tremendous red bang, and the world seemed to stop stock-still for a moment. Then things started with a rush. I realized that I was clinging, sprawling, to the wall, and that men were hurrying and scrambling out of the trench. I followed them out. This was about 11:30 a. m. I was in a queer 'semidetached' sort of condition. I just clung desperately to the idea, 'I must finish my turn of duty.' (I was on duty at the time.) This idea obsessed my mind to the exclusion of all others. I did in fact finish my turn, and then returned to my dug-out and slept or dozed until I was roused by my company commander to take a turn of duty at 1 o'clock next morning until 3, which I did. I then returned to my dug-out and slept and dozed until we came out of the trenches. I walked, carrying all my equipment and pack, for about 100 yards, and then had to be supported to headquarters, where a stretcher conveyed me to the advanced dressing station. I had a headache at the base of my skull from ear to ear, and the ground behaved like the deck of a sailing yacht in a stiff breeze: that is, it seemed to slant sharply away to the right and at the same time to pitch. During the time in the trenches I had a curious freak of memory. A number of events occurred which I remember quite well, but not as having occurred then. If I may employ a simile, they are like beads of a broken necklace, which have slipped from the thread and are lying loose. For instance, one of the other subalterns recalled to my mind that I had paid him a flying visit in the trenches subsequent to my accident. I then remembered perfectly well having paid the visit, but I had no idea that it was in that time. He also reminded me of our colonel dodging shells. I quite remember the incident, but cannot place it in that time.
>
> "One other rather horrible feature of this business has been a sort of nightmare. I have not had it for some time now, for which I am profoundly thankful. These things were not nightmares, and they occurred several times. I would allow myself to doze in the dark at night and I would suddenly realize that I was sinking slowly to a most unthinkable, dreadful place, and there were things there that were too unpleasant to even write about. I knew that if I did not make an effort to get out I would never manage it. I made prodigious struggles and broke away from it, but in the dark I couldn't be sure whether or not I was quite clear of it, and I would find myself partly out of bed and in a state of most childish alarm. I therefore tried to avoid sleeping at night and succeeded quite well. The only other symptom of any interest is that when I turn about to the right, the horizon rushes past with an unsteadying effect: whereas the other way is not abnormal."

Recumbent, the examination was negative in every particular. Dr. Ashdowne, under whose charge he was, thought the reflexes on one side were perhaps a little increased; but the point of special interest was the extraordinary gait, with the feet far apart, the arms out, the man balancing himself, and making several attempts with the hind foot before taking a step. Not long after the accident he was seen by Dr. Gordon Holmes, who thought possibly there was a cerebellar shock. He is gradually recovering, and the gait has now become much nearer natural.

Functional Spasm of Leg Muscles.—After a slight attack of trench rheumatism in the middle of February, a man had frost-bite which did not proceed to necrosis, but which left him with both feet very painful, so that he could not walk. The right foot has recovered, though the sole is still a little sensitive. On examination, May 18, he was a very healthy looking man; recumbent, the legs looked normal, but perhaps the left was a little smaller. When he was asked to lift the leg from the bed, the muscles immediately went into spasm and remained rigid. The vastus externus stood out with great prominence, and when the effort was relaxed, the spasm evidently remained in it for a longer period. The muscles were not painful; the stocking anesthesia was gradually disappearing. He could walk, but carried the leg very stiffly, and could scarcely take a step on account of the pain in the sole. The other leg had not been involved. The deep and superficial reflexes were present, perhaps a little exaggerated.

At Blenheim there was a man, aged 23, who had rheumatism and cold-bite in the feet in December, with great tenderness. For several months he had persistent spasm of the anterior tibials on both sides. He could not straighten the foot voluntarily, and passively it could be done only with the strongest effort. The anterior tibials stood out with great prominence. The knee jerks were + +. There was no Babinski or ankle clonus. He could walk on his heels, but with difficulty. There was plantar hyperesthesia. He gradually improved, and the spasm lessened with massage and electricity.

At Milton Hill, a man after frost-bite had a spasm of the muscles causing talipes, so that he walked on the outer edge of the foot. Any attempt to straighten it caused him pain and spasm. He, too, had had a stocking anesthesia and symptoms of neurasthenia. Evidently the trench warfare is a nerve-racking business, causing all forms of troubles from mild nervous break-down to the severest types of functional disorder. In many cases, tobacco is a factor. The hardened veteran may smoke from twenty to thirty cigarets a day without inconvenience, but the unseasoned soldier cannot stand such excess. Among the convalescents, many cases of rapid pulse and slight anemia are, I believe, due to tobacco. Special provision is to be made for the nervous cases, on which a group of experts is already at work.

GAS POISONING

I have referred to the inefficiency of the modern rifle bullet as a weapon of war. The high-explosive shells, the hand grenades and the shrapnel do damage enough; but now comes the barbarous device with which men try to kill each other by the use of poisonous gases. Under date of May 4, General French reported the use of gases ejected from pipes laid into the trenches. "The effect of this poison is not merely disabling or even painlessly fatal, as suggested in the German press. Those of its victims who do not succumb on the field, and can be brought to hospital, suffer acutely, and in the larger proportion of cases die a lingering and painful death. Those of its victims who survive are in little better case, as the injury to their lungs appears to be of a permanent character." The reports of acute cases describe a suffocative edema of the lungs of an appalling character. Both the Hon. Robert Bacon, late minister to France, and Dr. Harvey Cushing speak of the sufferings of the victims as passing all belief—an incessant gasping for breath, cough, and the expectoration of a thin, blood-stained albuminous fluid. The mortality is high, but in a great many mild cases there is recovery, and the patients have been sent across. I have seen about thirty. Only three cases were severe; one patient had slight cyanosis, dyspnea, and many fine bronchitic râles; two had bronchitis. The other patients were convalescent, and nothing amiss could be determined on physical examination; but in several cases there was functional disability, shown by dyspnea on the slightest exertion. One man had suppression of the breath sounds; neither the inspiratory nor the expiratory murmurs could be heard distinctly. I should say that the prognosis was good in a majority of these cases. Anatomically, it is an acute bronchitis and bronchiolitis with exudation of a highly albuminous fluid into the tissues and air cells. In Dr. Haldane's laboratory I was shown sections from two lungs which presented the most extraordinary fragmentation of the alveoli. Macroscopically, the cut surface looked like emphysema, and there were air blebs beneath the pleura. The gas appears to be chlorin, which is irrespirable in dilutions of 1:10,000. Masks saturated with solutions of sodium hyperchlorid, with glycerin to keep the material moist, appear to be an efficient protection. Certainly the gas is a great addition to the "frightfulness" of war, but it is to be hoped that the Allies may not be forced to adopt such measures of scientific barbarism.

PARIS LETTER

Paris, May 20, 1915.

The War

THE WAR AND THE MEDICAL STUDENTS

A decree of 1902 authorizes the appointment to the grade of assistant physician (which corresponds to the grade of noncommissioned officer), in case of mobilization, medical students who have taken not less than three years of medical work toward their doctor's degree. Accordingly, all medical students who have this amount of work to their credit have been, except in cases in which there were special reasons for the contrary, appointed to this grade. Notwithstanding, the number of these medical officers has become insufficient because of the losses undergone by the medical service, which have borne heavily on the assistant physicians, and also because of the appointment of a certain number of these physicians to the grade of *aide-major* (sublieutenant). To supply the ever-increasing need of the medical service, it has been decided to reduce the requirements for the position of assistant physician. The president of the republic has therefore signed a new decree which authorizes the appointment during the war as assistant physicians, either in the field or in hospitals, of medical students who have had two years' work.

The minister of war has decided that medical students who have had not less than a year's work and who are at present mobilized either in the interior zone or in the zone of the armies may be released from their present duties to be employed in the medical service either as litter bearers or as nurses.

THE WAR AND ADVERTISEMENTS FOR FOODSTUFFS

The head of the service at the prefecture of police for the suppression of frauds has been designated by the minister of agriculture to institute investigations into the quality of milk, foods and drinks sold in the zone of the armies either to the soldiers or to the inhabitants.

Since the beginning of hostilities a certain number of manufacturers have been exploiting special food products which are offered to the public as possessing remarkably superior nutritive qualities and as supplying in small volume the place of large quantities of foods which have the reputation of being nutritious. These products are advertised particularly as foods for soldiers and children. The service for the suppression of frauds has analyzed these specialties with results which should be generally known. While none of these preparations seems to be actually harmful and while some—the minority—have actual nutritive advantages, analysis shows that most of them have no such especial nutritive value as is claimed for them in the advertisements. The documents in about twenty of these cases have been laid before the attorney-general, and the manufacturers in question have been notified to cease manufacturing and selling these products immediately.

INTOXICATION BY IRRITATING GASES

Drs. A. Dujarric de la Rivière and J. Leclerq had the opportunity of seeing at Calais a number of soldiers who have been subjected to the action of irritating gases (bromin and chlorin vapors) used by the Germans at Langhemarch. Frequently, in addition to the bronchial or pulmonary phenomena, there was hepatic or renal involvement. In many patients, the pulmonary phenomena consisted of an inflammation of all the respiratory tubes, including even the finest bronchial ramifications. Two patients presented the clinical picture of hemolytic icterus and a third during several days had hemoglobinuria. Several others had persistent attacks of albuminuria. Dr. Henrot of Reims has presented before the Académie de médecine a valved respiratory mask which protects the wearer from the asphyxiating vapors.

WOUNDS OF THE HEAD BY BALLS AND FRAGMENTS OF SHELLS

At one of the last sessions of the Société de chirurgie de Paris, Dr. Vinay, surgeon of Mont-Dore, called attention to the fact that men wounded in the head should receive a very strict examination. Many such patients during the first few days show no symptoms likely to arouse suspicion of an underlying lesion of the skull and brain; often it is only after the appearance of secondary infectious phenomena that operation is performed, and then it is frequently too late. There is, therefore, good reason for early operation, but, to avoid useless exploration and operation in cases in which no good can be done, Vinay advises the following line of procedure: In bullet wounds of the head, except lesions which are evidently superficial, a large flap of the scalp should always be turned back so that the skull may be examined. In the majority of cases a lesion of the skull will be found and will then be trephined. Wounds produced by fragments of shell should be explored with a probe and the skull should be systematically examined if the probe strikes directly on a bone. In most cases this will lead to a trephining operation which would have become imperative a few days later. By following these rules one is sure to extract fragments, disinfect the wound and drain it in season. If one happens to find an uninjured skull (which is the case about one time out of ten) a few stitches will repair all the damage without injury to the wounded.

MILITARY PHYSICIANS AND THE LEGION OF HONOR

Among the physicians on the rolls of the Legion of Honor are Dr. Quénu, professor of clinical surgery at the Faculté de médecine de Paris and principal physician of the second class (which corresponds to the grade of lieutenant-colonel) in the military government of Paris, and Dr. Potherat, surgeon of the hospitals of Paris, who as head physician of an ambulance at first at Nancy, then on the Marne and finally on the front of his army corps, "has rendered truly exceptional service."

DEATH OF DR. ALBERT BILLET

Dr. Albert Billet, principal physician of the first class and director of the medical service in the fifteenth army corps, has just died at the military hospital of Val-de-Grâce of the results of a disease contracted in service. He was a distinguished scientist and has left a great number of works dealing chiefly with the prophylaxis of epidemic and exotic diseases which have won him numerous distinctions from the Académie de médecine and the Académie des sciences.

BERLIN LETTER

Berlin, May 11, 1915.

Personal

Prof. F. Külbs, the present assistant at the first medical clinic at Berlin, has been called to Strassburg as director of the medical policlinic, to succeed Prof. Erich Meyer.

May 4, Ernst Haeckel completed his fiftieth year as regular professor of zoology at the University of Jena. The anniversary was saddened for him by the death of his second wife a few days before. He is 81 and is still in full mental vigor. Since 1907 he has been entitled to be called *Excellenz.*

The ophthalmologist, Prof. J. Stilling, died at Strassburg, May 3, aged 73. He was the son of Benedikt Stilling, a leading anatomist and surgeon in his day. Professor Stilling's most important works were on color blindness. His tables for testing vision for colors in candidates for railroad and marine positions are in common use not only in Germany, but in other countries, and have already passed through sixteen editions. Other popular works of his are a manual on the principles of ophthalmology and reports of research on the origin of myopia, glaucoma, etc.

Causes of Death in Prussia, 1913

The vital statistics for Prussia show that the death rate during 1913 from diseases of the digestive organs was 17.39 per 10,000 inhabitants (15.94 in 1912); from old age, 15.71 (17.37); from diseases of the circulatory organs, 15.09 (15.44); tuberculosis, 13.65 (14.58); pneumonia, 12.03 (13.48); cerebral hemorrhage and other affections of the nervous system, 10.31 (10.57); congenital debility, 10.25 (10.55); cancer and other neoplasms, 8.24 (8.15); diseases of the respiratory organs, 7.85 (8.69); accidents, 4.06 (4.07); diseases of the urinary and genital organs, 2.87 (2.86); suicide, 2.21 (2.12); whooping cough, 1.89 (2.31); diphtheria and croup, 1.81 (2.04); measles, 1.75 (0.46); scarlet fever, 1.08 (1.04); puerperal fever, 0.96 (0.99); erysipelas and other wound infections, 0.92 (0.97); influenza, 0.72 (1.12); typhus, 0.34 (0.38); other contagious diseases, 0.34 (0.33); violent deaths, 0.21 (0.20); contagion from animals' diseases, 0.01 (0.01); other known causes of death, 15.89 (16.30), and unknown causes, 3.39 (3.94).

The War

THE FOOD SUPPLY

A number of recent decrees demonstrate that the food supply is becoming more fully assured. The price of flour has been reduced, and for wheat flour more than for rye flour, in order to bring the comparatively ample supply of wheat flour within the reach of the less well to do. An order was promulgated a while ago that communities should put up meat so that it would keep, but this order has been rescinded, as the supply of cattle is ample in every respect, so that precautionary measures of this kind are unnecessary.

At Berlin the bakers are no longer permitted to mix fresh potatoes in their bread dough, but potato flour can still be used. Our bread consequently begins to taste nearly natural once more. The price of all the other foodstuffs and delicacies is but little above ordinary prices, and there is no lack in any direction, the fluctuations at first being now all straightened out.

FINANCING THE FAMILIES OF PHYSICIANS ABSENT ON MILITARY SERVICE

The efforts of the profession to come to the timely financial aid of the physicians serving in the field are continued in different parts of the country. At Berlin, the Kuratorium for war absentees, organized for this purpose, has realized remarkably successful results already with the associations with which it has had dealings. The organized free-choice insurance physicians have agreed to pay the Kuratorium 10 per cent., and the Verein of Berlin insurance physicians has agreed to pay 5 per cent. of their insurance fees for the year 1915. The central organization of insurance physicians has also commended to its affiliated groups that they place 5 or 10 per cent. of their income from the insurance societies at the disposal of the Kuratorium for the period of one year. By this means, including the 55,000 marks already subscribed by the medical chambers, there will be approximately 300,000 marks on hand for the war relief emergency fund for the absentees. All the other physicians of greater Berlin are now being solicited by a subcommission to learn how much can be depended on from others outside of those under contract with the insurance societies. It is anticipated that several times the amount subscribed by the Aerztekammer will be pledged.

LONDON LETTER

London, May 21, 1915.

The War

THE KING GEORGE HOSPITAL

Though all the permanent hospitals of the country have placed a large part of their accommodation at the service of the War Office, the number of wounded from this colossal war is expected to be so great that special hospitals are being erected. Of these the largest is the King George Hospital in London, which, as mentioned in a previous letter to The Journal, is the result of the conversion of a building intended for the new Stationery Office of the government. It will accommodate 1,600 patients, and the floor space is so great that 9½ acres of linoleum are required. The hospital is divided into five floors, the first being medical and the remaining four surgical. There are two operating theaters on each floor, one for septic and the other for nonseptic cases. There are special departments of all kinds and a magnificent Roentgen-ray department in the basement. The vast roof is converted into a garden with revolving shelters in which the sick can enjoy in the long summer days the coolness of a high altitude without discomfort from the wind.

PRECAUTIONS AGAINST AIR RAIDS

The German method of attack has rendered necessary the taking of precautions in London against a Zeppelin raid. The following steps have been adopted on the recommendation of the Royal Society of Medicine: It has been ascertained what hospitals, infirmaries and dispensaries could do in the event of civilians being injured in their neighborhood, first, in the matter of provision for first aid, how many individuals they could receive and treat, then to be transferred as quickly as possible to their homes, to hospitals, or to nursing homes; and secondly, how many they could receive for complete treatment. A map of the London area has been prepared and marked, showing these receiving centers with the number of cases receivable. If the map revealed that any district had no receiving center, say within a radius of one mile, application was made to the local authorities inviting them to provide some suitable place—a town hall, a public bath, a library or a school—to which the police and helpers might be directed to convey the injured. The local authorities would provide an adequate supply of the material required for first aid, and the committee have drawn up a list of such material with prices, and have arranged with some surgical supply company to provide it at cost price. Emergency centers have been marked on the map, and copies of the map or full topographic particulars have been sent to every police office. A list of surgeons, physicians and district nurses willing to help in each district has been prepared, with names and full addresses, and (when possible) telephone numbers, and a copy of each district list has been sent to each police office in the district.

THE SONS OF PHYSICIANS KILLED IN THE WAR

The medical profession has already a considerable death roll of its members killed in the discharge of their duties at the front. To this must be added the sad bereavement of the loss of sons who are combatants, in some cases only sons. Among the well-known members of the profession who have thus lost their sons are Dr. Lewis Jones, Sir Wilmot Herringham, Dr. Norman Moore, Dr. H. D. Rolleston, Sir James Barr, Mr. W. H. Battle, Dr. A. E. Garrod and Dr. Lauriston Shaw.

Association News

THE SAN FRANCISCO SESSION

An Invitation from Tacoma

The Pierce County (Washington) Medical Society extends a cordial invitation to the Fellows of the American Medical Association who attend the San Francisco session to stop over in Tacoma on their way to or from San Francisco. Dr. James R. Yocum, Box 1040, Tacoma, chairman of a committee of this society on entertainment, advises that if a few days' notice can be given, it will be glad to take visitors for a short trip on Puget Sound, or if preferred, on automobile rides about the city. The committee especially requests that parties, traveling by special train or by special car, give notice of the time when they are likely to reach Tacoma. The committee will also be glad to assist in making arrangements for trips by either rail or automobile to Rainier National Park or Mount Tacoma. For this trip, the railroad fare is $5; fare by automobile for the round trip to the inn, $6; to the foot of the glacier, $7; to Paradise Valley, $8. The trip by train takes part of each of two days. The automobile trip can easily be made in one day.

Marriages

George Ward Disbrow, M.D., Newark, N. J., to Miss Virginia W. Sprecher of Sykesville, Md., in Washington, D. C., May 23.

Capt. Floyd Kramer, M. C., U. S. Army, to Miss Dorothy Millikin Bevans, at Fort H. G. Wright, Fisher's Island, N. Y., May 25.

Edward Newman Roberts, M.D., Pocatello, Ida., to Miss Florence Bloom of West Burlington, Ia., May 27.

David Linn Edsall, M.D., Boston, to Miss Pendleton Kennedy of Washington, D. C., June 2.

Alfred Hoff, M.D., St. Paul, to Mrs. Merrun Dyer, at St. Luke's Hospital, St. Paul, recently.

Thomas Joseph Toner, M.D., Gary, Ind., to Miss Alma M. Hoffmeister of St. Louis, June 8.

Isaac W. Brewer, M.D., to Miss Charlotte Underhill of Bath, N. Y., June 8.

Ernest Lackner, M.D., to Mrs. Carrie Klein, both of Chicago, June 3.

Isidor Heller, M.D., to Miss Ida Engel, both of Brooklyn, June 1.

Deaths

Lewis C. S. Turner, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1882; a Fellow of the American Medical Association and once president of the Jasper County (Ia.) Medical Society; for thirty years a practitioner of Colfax, Ia., and for fourteen years of that time medical director of the Victoria Sanitarium; for many years health officer of Colfax and for three years a member of the local school board; died in the Mount Pleasant (Ia.) State Hospital, May 18, from arteriosclerosis, aged 60.

Fayette Hamilton Peck, M.D. New York University, New York City, 1881; a Fellow of the American Medical Association; surgeon in chief of the Utica and Mohawk Valley Electric Railway Company; local surgeon of the New York Central Lines; senior surgeon to St. Luke's Hospital and gynecologist to and president of the medical staff of the Utica City General Hospital; formerly health officer of Utica, N. Y.; died at his home in that city, May 24, from heart disease, aged 59.

James MacArthur, M.D. Queen's University, Kingston, Ont., 1878; president and for many years a member of the Ontario Medical Council; one of the founders of the London (Ont.) Medical Association; jail physician of London for more than fifteen years; died at his home in London, May 23, from heart disease, aged 60.

William James Gills, M.D. University College of Medicine, Richmond, Va., 1901; a member of the Medical Society of Virginia and secretary of the Mettauer Medical Society; formerly surgeon of the Third Battalion, Seventieth Infantry, Virginia Volunteers; physician to the almshouse of Prince Edward County, Va.; formerly a member of the town council of Farmville, Va.; died in the Johnston-Willis Sanitarium, Richmond, Va., May 22, from pellagra, aged 37.

Henry Bak, M.D. University of Vienna, Austria, 1872; formerly a surgeon in the Austro-Hungarian army and later a surgeon of volunteers during the Spanish-American War; president of the faculty and professor of practice of medicine and pediatrics in the Southern College of Medicine and Surgery, Atlanta, Ga.; for several years a practitioner of Chicago; died in the Michael Reese Hospital in that city, May 25, from carcinoma of the bladder, aged 68.

James Orton Edie, M.D. Jefferson Medical College, 1874; a member of the Michigan State Medical Society and Grand Rapids Academy of Medicine; formerly local surgeon at Grand Rapids of the Lake Shore and Michigan Southern Railway; consulting surgeon to the Butterworth Hospital and consulting physician to the Union Benevolent Association Hospital, Grand Rapids; who recently moved to Everett, Wash.; died in that city, May 25, aged 77.

James Francis Jacob, M.D. Jefferson Medical College, 1893; of Throop, Pa.; a Fellow of the American Medical Association and one of the best known Mid-Valley practitioners; one of the leaders in the work of caring for the widows and orphans of the great Pancoast disaster and since that time instructor in first aid at the mines; died in the Burns Private Hospital, Scranton, May 24, two days after an operation for gallstones, aged 44.

William Monroe Carling, M.D. Medico-Chirurgical College of Philadelphia, 1897; of Battle Creek; a member of the Michigan State Medical Society and the Southwestern Michigan Triological Society; formerly clinical assistant in ophthalmology in the Denver and Gross College of Medicine of the University of Denver, Colo.; a specialist on diseases of the eye, ear, nose and throat; dropped dead while playing golf at Battle Creek, Mich., May 30, aged 42.

Orange Pomeroy, M.D. Cincinnati College of Medicine and Surgery, 1860; Bellevue Hospital Medical College, 1871; of Chardon, Ohio; assistant surgeon of the Sixteenth Ohio Volunteer Infantry during the Civil War; manager and for twenty years president of the Chardon Telephone Company; died at his winter home in St. Petersburg, Fla., May 17, aged 79.

Melvin S. Jones, M.D. Western Reserve University, Cleveland, 1877; for several years a practitioner of Battle Lake and Dead Lake, Minn.; a member of the legislature from Ottertail County, Minn., in 1902; for the last year a resident of Orange, Calif.; died at his home in that place, May 19, from heart disease, aged 60.

Julia W. Carpenter, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1870; a Fellow of the American Medical Association; president of the Cincinnati Obstetrical Society in 1902, and vice-president of the Cincinnati Academy of Medicine in 1904; died at her home in Walnut Hills, Cincinnati, May 23, aged 74.

William S. Stewart, M.D. Hospital College of Medicine, Louisville, Ky., 1895; of Pine Bluff, Ark.; a Fellow of the American Medical Association and secretary of the State Board of Medical Examiners of the Arkansas Medical Society; died in Hot Springs, Ark., May 31, from acute nephritis, aged 45.

Paul H. E. Sloan, M.D. Medical College of the State of South Carolina, Charleston, 1859; surgeon in the Confederate service throughout the Civil War, and later a physician and druggist of Pendleton, S. C.; for many years secretary and treasurer of Clemson College, Pendleton; died at his home, May 15, aged 79.

Charles Henry Rosenthal, M.D. Cooper Medical College, San Francisco, 1881; University of Leipzig, Germany, 1884; a Fellow of the American Medical Association and one of the most prominent practitioners of San Francisco; died at his home in Berkeley, Calif., May 24, from angina pectoris, aged 58.

William Marion Forman, M.D. University of Louisville, Ky., 1877; for many years a practitioner of Nelson County, Ky., and at one time deputy internal revenue collector in that county, but since 1896 a resident of Louisville; died at the home of his son in that city, May 24, from heart disease, aged 59.

J. F. Coughenour, (license, Mont., 1889); a veteran of the Civil War and a pioneer of Montana; in the early days clerk of the district court at Deer Lodge; later a practitioner of the Bitter Root Valley at Corvallis; died at his home in Hamilton, Mont., May 18, from cerebral hemorrhage, aged 71.

Reuben Robinson, M.D. University of Nebraska, Lincoln and Omaha, 1896; also a graduate in pharmacy; for several years a member of the teaching staff of his alma mater; formerly a member of the State Medical Association of Texas; died at his home in San Antonio, Texas, May 20, aged 54.

John Robertson McIntosh, M.D. University of Edinburgh, Scotland, 1888; of St. John, N. B.; a member of the American Ophthalmological Society; a specialist on diseases of the eye, ear, nose and throat; died at his home in St. John, May 20, from cerebral hemorrhage, aged 53.

John E. McCuaig, M.D. Queen's University, Kingston, Ont., 1891; well known as an alienist of northern Pennsylvania; for several years a member of the staff of the Danville (Pa.) State Hospital; died at his home in Erie, Pa., May 18, from uremia, aged 47.

Daniel E. Berryman, M.D. University of Edinburgh, Scotland, 1873; for more than forty years a practitioner of St. John, N. B., and since 1883 coroner for the City and County of St. John; died at his home in St. John, May 17, from cerebral hemorrhage, aged 68.

Francis P. Troxell, M.D. University of Pennsylvania, Philadelphia, 1865; a veteran of the Civil War; a practitioner of Allentown and later in the fire insurance business; for several years owner of a fruit farm at Pomona, Calif.; died in Los Angeles, May 14, aged 80.

David Ballantyne Anderson, M.D. Johns Hopkins University, Baltimore, 1913; of Salt Lake City, Utah; an intern in Mount Sinai Hospital, New York City; aged 27; was accidentally drowned during a heavy windstorm, May 26, while canoeing on Lake George.

Henry Martin Rising, M.D. Yale University, New Haven, Conn., 1868; a member of the Connecticut State Medical Society; for forty-five years a practitioner of South Glastonbury, Conn.; died at his home in that place, May 18, from arteriosclerosis, aged 71.

Emil Kunz (license, Illinois, 1891), a practitioner since 1877; a member of the German Medical Society of Chicago and a well-known anatomic draughtsman; died at his home in Chicago, May 25, from cerebral hemorrhage, aged 66.

William Green Torrence, M.D. Dearborn Medical College, Chicago, 1907; Leonard Medical College, Raleigh, N. C., 1908; a respected colored practitioner of Asheville, N. C.; died at his home in that city, about May 24, aged 34.

Henry Dare Moore, M.D. Jefferson Medical College, 1887; a Fellow of the American Medical Association and a member of the surgical staff of the Philadelphia Stomach Hospital; died at his home in Philadelphia, May 27, aged 50.

Sumner Carruth Saville, M.D. Harvard Medical School, 1894; a Fellow of the American Medical Association; and a well-known practitioner of Boston; died at the home of his mother in Cambridge, Mass., May 27, aged 47.

John Rice Eldridge, M.D. Cooper Medical College, San Francisco, 1894; a specialist on nervous and mental diseases; formerly a member of the faculty of his alma mater; died at his home in Berkeley, Calif., May 23, aged 50.

Hilliard J. Yarbrough, M.D. Eclectic Medical University of Kansas City, Mo., 1905; of Dallas, Tex.; formerly a member of the Board of Health of Ada, Okla.; died at the home of his niece in Dallas, Tex., May 23, aged 63.

James Henry Joyce, M.D. Tufts College Medical School, Boston, 1903; formerly a member of the Massachusetts Medical Society; city physician of Salem, Mass., since 1906; died at his home in that city, May 28, aged 34.

Alexander Ault, M.D. McGill University, Montreal, 1886; for more than forty years a practitioner of Oshkosh, Wis.; but since 1908, a resident of Brooklyn; died at the home of his daughter in that city, May 19, from cerebral hemorrhage, aged 77.

Thomas William Nave, M.D. Tulane University, New Orleans, 1900; formerly a Fellow of the American Medical Association; a member of the State Medical Association of Texas; died at his home in Galveston, Tex., May 13, aged 37.

Max A. Boesger, M.D. Western Reserve University, Cleveland, 1884; formerly a member of the city council of Cleveland and coroner of Cuyahoga County, Ohio; died May 18, at his home in Cleveland, from appendicitis, aged 54.

Isaac T. Rand, M.D. Tulane University, New Orleans, 1886; a member of the Louisiana State Medical Association and once president of the Attakapas Medical Society; died at his home in New Iberia, La., May 14, aged 49.

John Samuel Hood, M.D. University of Michigan, Ann Arbor, 1867; a veteran of the Civil War and in 1898 a member of the legislature from Fleming County, Ky.; died at his home in Neption, Ky., May 14, aged 75.

William T. S. Duvall (license, District of Columbia), a practitioner since 1865; from 1867 to 1882, an employee of the postoffice department, Washington; died in Garfield Hospital, Washington, D. C., May 16, aged 80.

Alfred Bland Tucker, M.D. Southern Medical College, Atlanta, Ga., 1886; Long Island College Hospital, 1887; a member of the Medical Society of Virginia; died at his home in Berryville, Va., May 14, aged 58.

Gilbert L. Parker, M.D. Jefferson Medical College, 1874; a veteran of the Civil War, at the close of which he retired from service with the rank of lieutenant-colonel; died at his home in Philadelphia, May 19, aged 82.

Daniel E. Fuller, M.D. University of Buffalo, 1878; a member of the Michigan State Medical Society; died at his home in Hastings, Mich., May 12, from a fever contracted during a sojourn in Florida, aged 58.

William Neilson, M.D. Harvard Medical School, 1872; a member of the Massachusetts Medical Society and for many years a practitioner of Leominster, Mass.; died in the Leominster Hospital, May 14, aged 74.

Hugh Thomas D'Arcy, M.D. Wisconsin College of Physicians and Surgeons, Milwaukee, 1897; for several years a practitioner of Bloomington, Ill.; died at his home in Chicago, May 13, from sciatic rheumatism.

T. J. Murray, M.D. Kentucky School of Medicine, Louisville, 1878; for many years health officer of Somerville County, Tex.; died at his home in Glen Rose, Tex., about May 6, aged 78.

Alexander S. Johnson, M.D. Southern Medical College, Atlanta, Ga., 1881; a physician and druggist of Bowman, Ga.; died at his home in that place, May 5, from cerebral hemorrhage, aged 59.

William S. Pearsall, M.D. New York Homeopathic Medical College, New York City, 1886; died at his home in Brimfield, Mass., February 18, from interstitial nephritis, aged 54.

Dudley O. Wedge, M.D. Jefferson Medical College, 1874; formerly of Ipava, Ill.; but since 1908 a resident of Chicago; died at the home of his daughter in that city, May 11.

C. W. Gotcher, M.D. Memphis Hospital Medical College, Memphis, Tenn., 1900; died at his home in Garza, near Denton, Tex., May 8, from heart disease, aged 41.

John M. Scott (license, Pa., 1881); a practitioner of Cabot, Pa., since 1871; died at his home in that place, May 20, from cerebral hemorrhage, aged 65.

Marion C. Castleberry, M.D. Gate City Medical College, Texarkana, Tex., 1904; died at his home in Harmony, Tex., April 4, from lobar pneumonia, aged 41.

Joseph Olmstead Allen, M.D. University of Buffalo, 1851; a retired practitioner of Fayette, Ohio; died at his home, May 20, from arteriosclerosis, aged 85.

Stephen Townsend, M.D. University of Wooster, Cleveland, 1891; died at his home in Columbus, Ohio, May 15, from cerebral hemorrhage, aged 67.

J. W. Bandel, M.D. Memphis Hospital Medical College, Memphis, Tenn., 1903; died recently at his home in Ramona, Okla., from cerebral hemorrhage.

Robert Roy McCall, M.D. Barnes Medical College, St. Louis, 1900; formerly of Fulton, Mo.; died at his home in Alameda, Calif., May 8, aged 36.

John Franklin Holt, M.D. Rush Medical College, 1884; of Assumption, Ill.; died at St. Mary's Hospital, Decatur, May 17, from diabetes, aged 75.

J. W. Bozeman, M.D. Medical College of Georgia, Augusta, 1849; died at his home in Marietta, Ga., March 6, from senile dementia, aged 89.

William C. Raynor, M.D. Hahnemann Medical College, Chicago, 1881; a veteran of the Civil War; died at his home in Milwaukee, Wis., May 12.

William Veloss Huffman, M.D. Jefferson Medical College, 1887; died at his home in Millersburg, Ky., May 16, aged 56.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

MORE EPILEPSY CURES

Some of the Less Important Nostrums of This Type

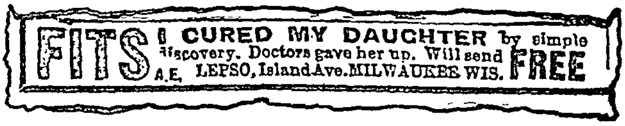
E-LEP-TINE

E-Lep-Tine is an epilepsy cure of the usual type. It is put on the market by the Miller Medicine Company, St. Mary's, Kan. This concern apparently has connected with it:

George Miller, M.D.
A. DeDonder
R. G. Erbacher

George Miller, according to our records, was graduated by the University of Pennsylvania in 1878. In addition to its "cure for fits" the Miller Medicine Company also puts out a purgative tablet "Rellim"—a rather obvious inversion of Miller. E-Lep-Tine has been marketed under the usual misleading claims, and there is nothing about the advertising matter to lift this product above the mediocrity of fraudulence common to epilepsy nostrums. "A large number of so-called 'cures' have been offered to afflicted persons," says the Miller Medicine Company, "but very few of them have effected any absolute cures." But:

> "Dr. Miller has to his credit now more cures than any practicing physician."



FITS I CURED MY DAUGHTER by simple discovery. Doctors gave her up. Will send FREE A.E. LEPSO, Island Ave. MILWAUKEE WIS.

The references in the advertising matter to the fact that taking E-Lep-Tine will produce drowsiness in the patient and, in certain instances, "cause small pimples to show on the body" naturally leads one to conclude that the essential drug in E-Lep-Tine, as might be expected, is some form of the bromids.

The Indiana State Board of Health in the second edition of its bulletin on "Medical Frauds" gives the following information regarding E-Lep-Tine:

Sodium and potassium bromides..........16 per cent.
Alcohol .... 6 per cent.
Ammonium valerate.

The Indiana chemists also state that while the price of this nostrum is $1.75, its value is 10 cents.

HERBETTA CURINE

Herbetta Curine is put on the market by the Herbetta Medicine Co., Indianapolis, Ind. According to the advertising matter:

> "Herbetta Curine is not an old remedy worked over. . . . it is not a nostrum or patent medicine. It is a scientific combination of four tablets discovered only after prolonged and diligent experience and research."

The company says that Herbetta Curine is not a cure-all; it is merely intended:

> "To improve the digestion and assimilation of food."
> "To restore tone and vigor to the wornout and exhausted nervous system."
> "To restore the natural action of the liver, kidneys and bowels."
> "To make rich blood."
> "To put health and life into the whole body."
> "To restore the sexual organs to their natural functions."

A specimen of Herbetta Curine was received from a correspondent recently. The package contained three envelopes labeled 1, 2 and 3, respectively, and in addition a number of red tablets. The following examination is reported by the Association's laboratory:

ENVELOPE No. 1:—This contained small, light green tablets. Tests indicated that these tablets contained a water-soluble phosphate of iron.

ENVELOPE No. 2:—This contained small gray tablets which were very bitter and probably consisted essentially, or largely, of some "bitter tonic."

ENVELOPE No. 3:—This contained small green tablets which responded to tests for aloes or aloin. These tablets constituted the laxative agent in the "treatment."

RED TABLETS:—These had a strong odor of sassafras and tests indicated that they were essentially strontium and potassium bromid.

Each "treatment" costs $5 and the company offers to issue a "guarantee" to the effect that after thirteen treatments are taken the victim may have subsequent treatments for $1.50 each "as long as treatment may be needed."

LEPSO

Lepso is sometimes advertised under the name of M. Lepso, Box 226, Milwaukee, Wis., and at other times by the Lepso Company, Island Avenue, Milwaukee. In addition to advertising in the cheap magazines the Lepso Company has obtained the names of victims by purchasing them from letter brokers. In this connection the following paragraph from a circular letter sent out by the Lepso Company is interesting.

> "A dealer in lists of names informed me that he had some names of people who are afflicted with Epilepsy for sale and he thought that I could use these names. I inquired as to how he happened to get his list of names and was informed that a so-called Epileptic Remedy company had sold them to him. So evidently once upon a time you must have answered an advertisement of a so-called company. It was certainly surprising for me to learn that these companies have no more loyalty or respect for the confidence of their customers than to betray them in this manner. As for myself, I would never think of selling the names of people who answer OUR ad. We keep all letters strictly confidential as any firm ought to have honor enough to do. Well, I got this list of names from this dealer because I know that our 'LEPSO' is a real fit remedy."

After a cursory analysis of Lepso in 1911 the Association's chemists reported:

> "Contains bromids equivalent to about 6.8 grams potassium bromid in each fluidounce."

As the dose recommended was one-half ounce, this was equivalent to giving 3.4 grams (51 grains) of potassium bromid to the dose. Such a dangerous mixture may be sold indiscriminately to the public without warning or even mention of presence of bromids.

Correspondence

Venarsen—A Disclaimer

To the Editor:—I enclose a pamphlet, received from the Venarsen Company, which states that venarsen is being used in the Vanderbilt Clinic by several men including myself.

Several weeks ago an agent of the Venarsen Company called to see me and I promised to give venarsen an experimental trial. The enclosed advertisement was sent to the profession actually before I had received the samples of venarsen. When the samples were received, they were not even opened, but were sent back to the company by express. You can see, therefore, that the Venarsen Company had no right whatsoever to use the names of any of the men associated with the Vanderbilt Clinic. Even if we had experimented with the drug and found it to be a valuable product, we would not allow our names to be used in this way. You can see therefore, that the company is entirely unscrupulous, and deserves to be severely chastised for misusing the names of reputable physicians.

I wish to say also that the publishers of the *Journal of Cutaneous Diseases* accepted a venarsen advertisement on a short contract. A short contract was given so that the advertisement could be discontinued if the Council on Pharmacy and Chemistry of the American Medical Association reported unfavorably on the product. We understand that the Council has reported unfavorably, and therefore, the venarsen advertisement will be removed from the *Journal of Cutaneous Diseases.*

This letter is approved by every physician you find on the pamphlet, and who belongs to the staff of the Vanderbilt Clinic. I wish that you would feel at liberty to publish this letter if you so desire, or to use it in any way you think advisable. GEORGE M. MACKEE, M.D., New York.

Editor, *Journal of Cutaneous Diseases.*

The Opera Glass in Roentgen Examination

To the Editor:—For the past year I have had occasion to examine a great many roentgenograms, mostly of the chest. I observed that certain shadows were more or less constant in the hilum of both lungs, more on the right than on the left. Trabeculae extending in all directions could be seen in most plates, but very indistinctly. It occurred to me that if one could magnify the plate in some way, the finer shadows could be brought out. I procured an ordinary pair of opera glasses, and placed the plate where a strong light, either artificial or natural, would bring out the shadows. Standing about 15 feet away and focusing the glasses, I obtained a much enlarged view of the plate, clearer in outline and an almost stereoscopic picture.

The advantages of this method of inspecting roentgenograms are:

1. A small picture could be taken to bring out the detail of the part to be examined and could be enlarged merely by looking at it with the opera glasses.
2. A clearer view will be obtained.
3. The picture is almost stereoscopic.
4. No expensive apparatus is necessary.

J. J. SINGER, M.D., St. Louis.

The Treatment of Lice of the Eyelashes and Brows by Hydrogen Peroxid

To the Editor:—In view of the increased interest in body parasites as a cause in transmitting disease, I wish to call attention to the great value of hydrogen peroxid in the treatment of pediculi ciliaris, or lice of the eyelashes and brows. My experience in the treatment of this disgusting pest with the various mercurial solutions and ointments usually recommended and employed for the purpose of destroying these parasites has not been satisfactory. While it is possible after a few days' use of mercurial preparations to destroy the lice, this does not rid the patient of the ova or nits. The treatment must be continued for days and weeks—until all of the ova are hatched. The ova cling tenaciously to the hairs, and the cause of the trouble is controlled if the ova are removed at once. By the application of a ten volume strength of hydrogen peroxid simply by mopping the eyelashes or brows with the solution on absorbent cotton and then passing the hairs through a pair of sterilized Kuhnt's or Noyes' trachoma forceps, the living parasites and ova will be removed in a few minutes, thus putting a quick end to the affection. There is no danger of bleaching the hair, from this limited use of hydrogen peroxid.

EDWARD L. MEIERHOF, M.D., New York.

Preventive or Prophylactic Packet in the Navy

To the Editor:—Apropos of the recent circular letter of the Secretary of the Navy to the commanding officers, in which that official refuses to authorize the issue of the "preventive or prophylactic packet" to the sailors on our war ships, I wish to inquire whether it is not possible to change the method of furnishing this packet so that the responsibility for its use would be squarely placed where it belongs—wholly on the men who use it? I grant that it is questionable whether the government should countenance immorality by providing against the consequences thereof. At the same time if the use of this packet is discontinued, this discontinuance will indubitably have as a practical result a greater incidence of disease. On the other hand its use, as is well known, has resulted and would continue to result in conserving health and effecting a considerable economy.

It is manifest that sailors must have the same use of their freedom as the ordinary citizen and every man must determine his conduct for himself. The Secretary of the Navy must admit that in the present state of human progress, we have only a choice of evils and in such a case, duty bids us choose the least.

Could not the government, as represented by its officers, emphatically warn the soldiers and sailors of the dangerous results from illicit indulgence and while absolutely refusing to countenance any infraction of the moral law, place within the reach of all the "preventive packet" in such a manner that its use would be absolutely the individual act of the sailor or soldier?

I have only the knowledge of a civilian and a medical man on this subject, but am of the opinion that, if it is not already done in the Army and Navy, arrangements should be made whereby every man would have brought home to him a knowledge of the dangers and fateful consequences of venereal diseases. After this is done, every man must decide for himself as to his conduct.

I wish to raise the above question for consideration and discussion.

Yours very truly,

RICHARD DEWEY, M.D., Wauwatosa, Wis.

Sphygmomanometer Cuff in Intravenous Injections and Hyperemic Treatment

To the Editor:—In THE JOURNAL, Jan. 9, 1915, p. 182, was an abstract of an article on the use of the cuff of the sphygmomanometer to cause a venous stasis, in introducing a needle for intravenous injection. I have used this method for a couple of years, and I believe the main part of its usefulness is the fact that by covering the release valve with a sterile towel, the pressure in intravenous injection can be relieved without breaking aseptic technic or requiring the assistance of a second person.

Also I find this apparatus to be very efficient in giving Bier's hyperemic treatment, because a definite venous stasis can be regulated by the definite pressure in the arterial supply, thus eliminating the guesswork which is evident with the old tourniquet method for producing hyperemia.

ARTHUR A. RANG, M.D., Washington, Ind.

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THE HARRISON NARCOTIC LAW

A PROTEST AGAINST THE ANNUAL FEE

To the Editor:—I have addressed the following inquiry to the Secretary of the Treasury. I have no fault to find with the provisions of the Harrison law, and in line with your editorial suggestions I believe that the profession should willingly give what time and trouble is necessary to carry out its provisions. I do believe, however, that it is time *for the profession to rise in mighty protest against the petty exactions* which are being piled on by the authority "Regulation" (and even without), for it is news to me that laws can be amended and amplified by any executive power, as is most certainly being done. H. S.

"*To the Secretary of the Treasury.*—Inasmuch as the Harrison law reads that 'on and after the first day of March, nineteen hundred and fifteen, every person . . . shall register, etc. . . . and on or before the first day of July, annually thereafter, . . . shall pay to the said collector a special tax, etc.,' I have the honor to inquire by what authority of law we are now required again to register, with the attendant trouble, expense and absurdity of being required to make per*sonal affidavit to a fact which is a matter of public record — i. e., our* legal qualifications to practice medicine.

ANSWER.—The protest of our correspondent is evidently called out by a circular letter recently sent out by the collectors of internal revenue of the various districts to all persons liable for internal revenue taxes. Physicians registered under the Harrison law are called on for the payment of the annual special tax of $1 imposed by that law. The law provides that at the time of registration and on or before the first day of July annually thereafter, every person who handles any of the specified drugs shall pay to the collector of his district a special tax at the rate of $1 per annum. As has been previously explained, the law went into effect March 1, 1915. The fiscal year of the United States government runs from July 1 to June 30. Consequently, the tax for the fraction of the year from March 1, 1915, to July 1, 1915, was prorated, each person registering paying 34 cents for the fraction of the year. It was explained at the time that a further payment of $1 would be necessary on or before July 1. This payment will cover the special tax until July 1, 1916, when another payment will be necessary. Consequently, the letter sent out by the collectors of internal revenue of the different districts is not a demand for reregistration, but is simply a notice for the payment of the annual tax. The receipt for the payment of this tax, like all internal revenue taxes, is in the form of a special tax stamp. This method of collecting taxes is the same for all persons affected by internal revenue measures. The letter sent out by the collector of internal revenue for the Chicago district went to 70,000 taxpayers in this district alone, including proprietors of theaters, shows, billiard and pool tables, bowling alleys, dealers in tobacco, liquor, oleomargarin, physicians, druggists, dentists and others. It was not a special measure applicable to physicians alone.

The application of an internal revenue tax to physicians is an entirely new proposition. It is not strange, therefore, that many physicians, like our correspondent, resent the necessary routine measures unavoidably connected with the collection of such a tax. It is well for a physician to remember, however, that the imposition of this small and nominal tax marks the first effort which has been made by the federal government to control the use of habit-forming drugs and to restrict them to legitimate purposes. The collection of this registration fee each year is a necessary part of the operation of the law. The circular to which our correspondent objects is simply a notification to persons registered under the law that the annual tax under the law is due and payable.

ALLEN METHOD OF TREATING DIABETES

To the Editor:—Can you send me or tell me where I can get literature on Allen's method of treating diabetes?

P. H. Greeley, M.D., Farmington, N. H.

To the Editor:—Please describe in full Allen's treatment for diabetes.

G. G. White, M.D., Elkaden, Iowa.

To the Editor:—How may I learn enough about the Allen starvation plan to use it? E. M.

Answer.—According to Allen, the first step is to fast—preferably in bed—until glycosuria ceases, and then for from twenty-four to forty-eight hours longer. Acidosis, if present, is thus rapidly reduced. Alcohol may be given during the fast, in the form of whisky or brandy. When the fasting patient has been free from glycosuria from twenty-four to forty-eight hours, the next step is to begin feeding very slowly and cautiously. A fixed program is unnecessary. It is desirable to establish the diet to suit the needs of the individual patient. The one requirement is that the patient must remain free from both glycosuria and acidosis. Any trace of sugar is the signal for a fast day. The original fast, to clear up the urine, may be anywhere from two to ten days in length, but after that no fast need be longer than one day. The factors to be considered in the diet are protein, carbohydrate, fat and bulk. Frequently the first thing given after the fast is carbohydrate. No distinction is necessary between different forms of starch, but there are advantages in using vegetables. The first day after fasting, the only food may be 200 gm. of vegetables of the class containing 5 and 6 per cent. of carbohydrates. This is increased day by day until a trace of glycosuria appears, which is checked by the fast day. The purpose of such a program is to learn the carbohydrate tolerance and to clear up the least trace of acidosis.

After the carbohydrate period, according to Allen, or sometimes in place of it, protein may be given. On the first day perhaps one or two eggs are given and nothing else. More protein, such as eggs and meat, is added day by day until the patient either shows glycosuria or reaches a safe protein ration. The purpose is to learn the protein tolerance and to regain protein lost as quickly as possible. Fat is somewhat less urgently needed except in weak and emaciated patients. It can be added gradually as conditions seem to indicate. An element of bulk in the diet is necessary to give a comfortable feeling of fulness and to prevent constipation. For this purpose, green vegetables are advantageous. When they are fed raw, cooked in steam, or boiled and evaporated, so that no water is thrown away, it is possible to estimate the quantity of carbohydrate, and the valuable salts remain. If the case is so severe that even green vegetables cannot be tolerated, the vegetables may be boiled through three waters, throwing away all the water. Nearly all starch is thus removed, and the most severe cases may take these thrice-cooked vegetables.

One result of the initial program described is loss of weight. The attempt to put on too much weight, according to Allen, is one of the sure ways of bringing back all symptoms, and is probably one of the chief causes of past failure in treating severe cases.

In brief, it is necessary to restrict all classes of food, and to test the tolerance of each patient in each particular class. Carbohydrate is given if possible, but is kept safely below the limit of tolerance. The following articles may be consulted:

Allen, F. M.: Studies Concerning Glycosuria and Diabetes, Boston, Harvard University Press, Cambridge, Mass., 1913, $9. (Theoretical and experimental; does not deal with treatment of patients.)

DENTAL CLINICS

To the Editor:—In The Journal, May 22, 1915, p. 1782, the statement is made, in reply to the inquiry of "R. B.," that "New York City has a number of school clinics maintained by the board of education, and there are four clinics in connection with the various hospitals, maintained by cooperation of the dentists and various philanthropic organizations of that city."

The facts are that the board of education has no dental clinics for schoolchildren. The board of health has seven dental clinics, six with paid dentists and one with a volunteer dentist in attendance. There are in New York City, aside from these municipal dental clinics, twenty-one clinics for the free dental treatment of schoolchildren.

I feel sure that there has been some misunderstanding on Dr. Ebersole's part regarding this matter and, on behalf of the Bureau of Child Hygiene of the Department of Health of New York City, I should like to have this correction made in the same column in which the original letter appeared.

S. Josephine Baker, M.D.,
Director, Bureau of Child Hygiene, New York.

LITERATURE ON MASTITIS

To the Editor:—Please give me references to articles on mastitis, with special consideration of the bacteriology, prophylaxis and treatment.

Adam P. Leighton, Jr., M.D., Portland, Maine.

Answer.—The following is a list of articles on this subject:

Human Evaluation.—The study of human values can only be made in the light of mankind's regard for itself. This has been, in all times, all ages and all countries, the lightest of human considerations. My observations lead me to believe that mankind has not improved the treatment of itself. The human sacrifice is required just as much today as it ever was in the Temple of Baal or on the altars of the Aztecs.—Seitz.

UNIVERSITY OF MINNESOTA AND THE MAYO FOUNDATION

Last February it was announced that William J. Mayo and Charles H. Mayo of Rochester, Minn., had set aside $1,500,000 to establish what was called the Mayo Foundation for Medical Education and Research and had offered to turn this foundation over to the University of Minnesota. A special committee was appointed by the board of regents of the university to make a thorough investigation of the matter and that committee has reported. The following is an abstract of the report:

Abstract of Report

The committee recommends that for a trial period of six years the university establish a part of its graduate work at Rochester, appoint investigators and teachers, set standards of work and graduation, and accept the maintenance funds, quarters, equipment and other opportunities offered by the Mayo foundation.

The committee further recommends that in case the experiment proves successful the work be continued on a permanent basis under these conditions: (1) complete control by the regents of endowment funds and income; (2) appointment by the regents of all directors, teachers, investigators and others connected with the Mayo foundation; (3) the maintenance at Rochester, Minn., of quarters and administration for the foundation work, with right to make from the endowment income appropriations for medical investigation anywhere inside or outside the state.

It is believed that through this policy the university would fulfil a public duty by: (*a*) providing notable facilities for advanced medical training; (*b*) standardizing and controlling in the public interest the preparation of medical specialists; (*c*) fostering medical research not only on a state but on a national basis; (*d*) furthering the growth of graduate work on the university campus, and (*e*) increasing the efficiency of undergraduate teaching at the university.

The committee presented the following educational considerations as the basis of its recommendations:

GRADUATE WORK IN MEDICINE

There seems to be uncertainty in many minds as to just what is meant by graduate work in medicine. So-called "postgraduate" courses in "polyclinic" schools are brief courses for busy practitioners who desire to keep "up to date," but these courses do not approach true graduate work in seriousness, or length of time or advanced character of instruction.

A graduate student in chemistry, history or any other branch of learning spends from two to five years in thorough training, and devotes a good part of his time to original investigation of a chosen topic. Graduate instruction in this sense is being extended to medicine.

Unlike undergraduate teaching, graduate instruction is not given in classes or in a fixed course of study. The essential point of the training is its individual character. Opportunities for such work are measured by the number and control of properly selected cases, by the character of the teachers, and by the character of the organization conducting the work.

In graduate work of any kind research plays a large part. Originality and ability to conduct investigation must be demonstrated.

The studies of a medical graduate in any given specialty should consist of: (1) Further work in the fundamental sciences of anatomy, physiology, etc.; (2) adequate practice in the technical procedures of diagnosis and treatment; (3) a thorough acquaintance with the literature of the specialty and related branches; (4) original investigation relating to his specialty.

Medical knowledge has become too extensive for any one to become a master of all of it. Such knowledge is still being increased by the discovery of new facts coming from systematic study by trained investigators. Investigators are trained by doing original work under critical and inspired leadership. This is the prime function of the graduate school. Again, adequate training must be provided for the men who desire to follow teaching as a career.

Heretofore, so far as special training is concerned, the best specialists have been, by force of circumstances, self-made. Success has depended more on native ability than on systematic training.

Not only does the profession lack standards, but the public has no way to judge as to the competency of special practitioners. The establishing of authoritative standards is needed for the protection of the public.

It is the duty of the university to extend the bounds of knowledge in this difficult field of medicine, and to do so, trained investigators are necessary. Again, it is the duty of the university to standardize graduate medical instruction.

The first duty of the medical school is to provide a thorough undergraduate course for the training of general practitioners, and as a basis for advanced work. Such a course demands laboratories, clinics and a highly trained staff. The provision of a first-rank undergraduate course involves a margin of leadership and facilities which can be used for a limited amount of graduate work also, and this cannot be developed beyond a certain point without great expense.

COST OF MEDICAL EDUCATION AT MINNESOTA

The medical plant of the University of Minnesota has already cost approximately $1,100,000. The clinical facilities have cost $300,000. The present annual budget of the medical school is $150,000, which includes a considerable expense for teaching done for other divisions of the university.

The cost of hospital and dispensary maintenance is $80,000 per annum. At least four-fifths of this amount is chargeable to the care of the indigent sick of the state, but by the legislature and in the public mind this is regarded as a part of the cost of medical education. On this basis the present total budget of medical education is $230,000 per annum.

The administrative board of the medical school have estimated that to round out the medical plant and double the present hospital facilities will cost for buildings $600,000 and for increased maintenance $60,000. To provide also for instruction and investigation a further annual cost of $40,000, which will bring the totals for plant and annual maintenance to $1,700,000 and $330,000, respectively.

It is evident that there must be a limit to the amount of state support. The extension of hospital facilities; the building and support of pavilions for women and for children, and the housing of the school for nurses ought to appeal to individual donors. If therefore the university is to provide graduate instruction and research for Minnesota and the Northwest, it must utilize all available facilities which can be controlled and standardized. But none of these latter can be regarded as substitutes for a university-controlled hospital and laboratory system for undergraduate instruction.

USE OF PRIVATE AND MUNICIPAL HOSPITALS

Municipal and private hospitals can be used in both undergraduate and graduate medical education to a limited extent and better arrangements may be made as time goes on. In the twin cities, however, the development of adequate facilities for clinical instruction of the advanced type in the municipal hospitals appears impracticable for some time to come. In private hospitals the work is rarely coordinated under one organization, the patients being considered as the individual cases of particular doctors. There is nothing which renders the private pay patient any less valuable for study than the charity patient, and in graduate teaching, where the student is a qualified and legalized physician and is the assistant of the teacher, there seems no reason why private patients should not be used. All the laboratory branches have conducted graduate work for several years. The work is standardized as a regular part of the graduate school of the university.

GRADUATE WORK AT MINNEAPOLIS AND ROCHESTER

In the clinical departments this type of work has recently been undertaken. All departments are now offering graduate work excepting those of dermatology and genito-urinary diseases. Six "teaching fellows" with aggregate stipends of $3,000, are giving their full time to the university. They do a small amount of teaching but devote the larger share of their energies to advanced study and research. There are two "graduate scholars" exempt from tuition fees, who devote half their time to graduate work.

The total number of graduate students in the medical school is twenty-one, of whom nineteen are candidates for the degree of M.S., Ph.D., or D.Sc.

Graduate work in the medical school is of importance not only for itself but also because of its stimulating effect on the faculty. It counteracts the deadening effect of undergraduate work, with its yearly repetition of elementary courses. It adds interest to teaching and keeps the faculty in active contact with research. Moreover, by such work the demand of the public for trained service is being met.

The Mayo foundation has well equipped laboratories in charge of full-time and thoroughly competent men. It has adequate library, museum, autopsy and editorial facilities, and it has at its disposal a wide range and large amount of clinical material in most respects representative. Although the patients are not charity patients the arrangements are admirable for affording graduate students the fullest advantages. They act as assistants to the permanent heads of clinical and laboratory services and are shifted from service to service so as to get full experience in all branches related to their major interest.

Under these conditions thirty salaried fellows and six voluntary workers are engaged in graduate medical study of a high degree of excellence. These men are qualified for enrolment in the graduate school of the university.

The staff of the foundation is composed of high-grade men. Several are recognized leaders in their special fields. Many of the staff have had teaching experience, and the group as a whole is scientifically and professionally on a par with medical facilities in the larger universities.

There is in Rochester a large amount of material in surgery, surgical pathology, gastro-intestinal diseases, goiter and Roentgen ray. There is also a large collection of clinical records systematically kept and so cross referenced as to be available for statistical studies. When it is realized that conclusions as to the causes and relations of diseased conditions can be drawn only by the comparison of large numbers of cases, the value of these records for medical research becomes apparent.

ADVANTAGES OF THE AFFILIATION

The facilities of the two institutions in large measure supplement each other. For all the specialties the university can furnish training in anatomy, physiology and pharmacology not available at Rochester. Thus the scientific foundation of the graduate students in both places would be assured. These students would constitute one body under the educational guidance of the dean of the graduate school. Such guidance is essential and cannot be supplied outside the graduate school of a university.

If the graduate work at Rochester passes to the control of the university, medical education in Minnesota will become a unit under the state university.

Advantageous cooperation between the clinical departments in the two places, with increased efficiency as a result of united facilities, are numerous. The following may be mentioned: In medicine the student would get at the university training in acute diseases and other conditions ordinarily found in the medical wards. This would be supplemented by experience at Rochester in the diagnosis and treatment of diseases not so frequently found in the University Hospital. The student desiring to specialize in women's diseases would be trained in obstetrics at the university and in gynecology both at the university and at Rochester. The training afforded in orthopedics at the hospital for the crippled and deformed at Phalen Park, under supervision of members of the university faculty, would be supplemented by the study of a somewhat different class of cases at Rochester. This is true in varying degree in all branches, for the quantity and kind of cases vary in the two clinics.

Educational efficiency would be improved by a freer exchange of staff members between the two institutions. Research workers could combine the appropriate materials of both places. The reciprocal stimulus of generous rivalry would be of value to both groups

THE UNIVERSITY TO CONTROL ALL MEDICAL EDUCATION

All forms of medical education in Minnesota, including graduate medical instruction, should be centralized in the university. The university should enter this new movement with conviction, extend to it the educational leadership which is needed and see to it that a university diploma shall be the recognized mark of proficiency in the medical specialties. It is reasonable to expect that the interchange of work between Minneapolis and Rochester, the possibilities of research and the presence of graduate students in both places would make it easier for the university to attract to its staff the best men from all parts of the country.

The effect on the undergraduate student body would be good. Ideals of research would be constantly before them. Able and ambitious students would be attracted to the undergraduate course because, while the graduate school is open to all medical graduates, those who come up through the university's own course of study and who establish high records would be most directly in line for fellowships and for laboratory appointments.

The extension of graduate teaching proposed would enable the university to serve the state by insuring more expert medical service to its people, by furthering research into cause, cure and prevention of disease, by protecting the public by a system of education, examinations, diplomas and degrees for specialists against incompetence and exploitation. The committee recommends, therefore, that the university establish graduate work at Rochester, Minn.; that such work be directed by the graduate school through its dean and the medical school graduate committee; that professors and other teachers be appointed on the nomination of the same committee, to carry on graduate teaching and research at Rochester, and that the offer of clinical and other facilities and gifts made by the Mayo foundation be accepted.

ABSTRACT OF FORMAL AGREEMENT

1. The agreement is made between William J. Mayo and Charles H. Mayo as Founders; the Mayo Foundation; Burt W. Eaton, George W. Granger and Harry J. Harwick, Trustees of the $1,500,000; and the University. It sets forth copies of the articles of the Foundation and of the two trust agreements and asserts or provides:

2. That the Mayos and their associates have entered into an agreement with the Foundation for the period of six years after Sept. 1, 1915, to pay all moneys and provide all subjects, facilities and material necessary to enable the Foundation to carry out its agreement with the University.

3. That the Board of Regents is by law required to manage the University and appoint its professors and employees and

fix their salaries and may accept in trust gifts and bequests on the terms and conditions on which they are granted.

4. That the University is maintaining a medical school and is carrying on graduate medical and surgical instruction and has determined to increase its faculty, secure additional facilities, sites and material, appoint additional professors and assistants and carry on part of the work of the school of medicine at Rochester.

5. That the Foundation gives and grants to the University free of charge the right to use for medical and surgical education and research space and rooms and equipment in a certain building in Rochester, together with all clinical and other materials and opportunities for graduate medical and surgical work available at the Mayo Clinic, St. Mary's Hospital, the Kahler Sanatorium and the Colonial Sanatorium in Rochester, for a period of six years after Sept. 1, 1915.

6. That the Foundation also agrees during that period to pay all salaries fixed by the Board of Regents and payable to professors, assistant professors and instructors appointed by the Board.

7. That until Sept. 1, 1921, the net income of each of the trust funds shall remain in the hands of the Trustees as an added increment to the principal of the funds.

8. That from and after Sept. 1, 1921, the principal of the funds and all accumulations to that date shall be turned over to and become the property of the University.

9. That the funds and the income therefrom are granted in trust to be used by the University as follows:

(a) The principal shall always be kept intact by the Board of Regents and be invested in suitable securities.

(b) The income from the funds shall be used for the purpose of graduate medical and surgical instruction and research carried on under the direction of the Board of Regents at Rochester, Minn., with the understanding that appropriations may be made for carrying on medical investigations anywhere within or outside of the state of Minnesota.

10. That the agreement may be terminated at any time on or before Sept. 1, 1921, on one year's notice given by either of the parties to the other, subject to the cooperation of all parties to discharge to the satisfaction of the University outstanding obligations to graduate students.

11. That the University accepts the gifts and grants, and obligates itself annually to furnish to the Foundation until Sept. 1, 1921, a budget stating the needs of this branch of the work at Rochester.

Massachusetts March Report

Dr. Walter P. Bowers, secretary of the Massachusetts Board of Registration in Medicine, reports the oral, practical and written examination held at Boston, March 9-11, 1915 The total number of subjects examined in was 13; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 68, of whom 40 passed, including 8 nongraduates and 6 osteopaths, and 28 failed, including 15 nongraduates and 2 osteopaths. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Chicago College of Medicine and Surgery	(1915)	76.1
Medical School of Maine	(1914)	75
College of Physicians and Surgeons, Baltimore	(1914)	78.6
Johns Hopkins University	(1913)	76.1
College of Phys. and Surgs., Boston (1912) 75;	(1914)	78.2
Harvard Univ. (1909) 75.2; (1913) 80.2, 83.2; (1914) 78.4;	(1915)	79.1
Tufts Coll. Med. School (1913) 81.2; (1914) 75, 75.2, 77.1, 78.2,		78.8
Univ. of Mich., Dept. of Med. and Surg (1894) 75;	(1912)	75.9
Dartmouth Medical School	(1900)	76.1
Albany Medical College	(1914)	80.7
University of the City of New York	(1880)	75
Jefferson Medical College	(1914)	80

Book Notices

Determination of Sex. By L. Doncaster, Sc.D. Cloth. Price, $2. Pp. 172, with 22 illustrations. New York: G. P. Putnam's Sons, 1914.

Those who wish a clear, critical and conservative exposition of the present scientific status of this ancient, yet ever new problem cannot do better than read this little book. The author is a well-known investigator in the field of the inheritance and determination of sex, and he therefore brings to the general treatment of the subject the sureness of the expert. At the same time he avoids dogmatism. The treatment is confined to the problems of sex determination in animals and man, and the author has "striven to avoid as far as possible the use of technicalities which might embarrass the untrained reader." The general argument will be everywhere intelligible to any well-educated person, even though certain special illustrative cases may require very close study. The book is an excellent antidote to some sensational and unscientific books.

As the author points out, there is no single character of living things, apart from the fundamental properties of life itself, so widely distributed as sex. Yet of its fundamental significance and function we have no real knowledge. It is commonly associated with reproduction, yet we may have reproduction without sex, and even sexual differentiation that is not associated with reproduction. The origin and significance of sex are utterly obscure problems in which no real recent progress has been made. On the other hand, the problem of sex determination, that is, of the causes which lead to the origin of individuals of one or the other sex, has advanced in many notable ways in recent years, so that it may be stated that certain of the causes are now well understood in many cases. The author does well in emphasizing the fact that the term "determination of sex" is used in two senses, namely, in the sense of ascertaining the causes of sexual differentiation, and in the sense of controlling the production of either sex at will. It is obvious that the causes when ascertained may turn out to be uncontrollable; indeed, much of the most important recent work leads to a decidedly pessimistic outlook for eventual control of sex production. But the author does not allow himself to be entirely convinced in this direction, and comes to the final conclusion that we may "regard the control of sex in man as an achievement not entirely impossible of realization." The facts which show that sex is determined by the germ cells either before or at the time of their union naturally receive the major consideration, because these facts constitute the newest and most precise data we have on the subject. There is presented evidence as to the stage at which sex is determined, the study of the inheritance of sex-limited characters, the problems of the inheritance of secondary sexual characters, the extraordinary facts concerning chromosome differences between male and female individuals, and the differentiation of the germ cells in such cases into male-determining and female-determining, all of which indicate an early determination of sex before the onset of embryonic development. Against these are set the data concerning atypical sex ratios, whether occurring in nature or under experiment, which seem to indicate an influence of external factors in sex determination. The collective data are then considered in a chapter in which the various theories are discussed in an admirable spirit, and the author's position is stated. The determination of sex in man comes up for separate consideration in the concluding chapter.

Chirurgische Operationslehre für Studierende und Aerzte. Von Prof. Dr. Friedrich Pels Leusden, ord. Prof. der Chirurgie. Second Edition. Paper. Price, 20 marks. Pp. 788 with 766 illustrations. Berlin: Urban and Schwarzenberg, 915.

This work was written chiefly for students and practitioners, but the author thinks the specialist as well will find in it something of value. Considerable new matter has been added in this edition, which is an improvement on the first; but this edition is open to the same criticisms which were made against the first, namely, it is distinctly a German work, and little that has originated outside of that country finds mention. The author recognizes this, but declares that he has not allowed patriotism to influence him. He then says: "I have taken great pains impartially to give authors due credit, but who will boast to so master even the entire literature of one's own country that an error might not slip in? That German literature is best known to me is self-evident, and therefore Germans in a German treatise have fared the best." As a partial excuse for errors in this direction, the author naively says, "If I have presented anything that is good which I have attributed to a wrong author I am sorry, but it doesn't change any that which is good." Many difficult and complicated operations remain unillustrated for the reason, as the author states, that "the beginner does not yet need them and the experienced operator can do without them." The same might well be said of most operations, but that principle does not contribute to the completeness of a work.

AMERICAN NEUROLOGICAL ASSOCIATION

Forty-First Annual Meeting, held at New York, May 6-8, 1915

(Concluded from page 1937)

Paralytic and Other Persistent Sequelae of Migraine

Dr. J. Ramsay Hunt, New York: In the vast majority of cases, a tendency to migraine entails no more serious consequences than the recurrence of periodic headaches of varying degrees of severity. Headaches of this character are often associated with curious transitory focal symptoms, as scotoma, hemianopsia, hemiparesis and hemiparesthesia. More rarely, evanescent aphasic attacks and mental disturbances accompany the attack. These focal manifestations are purely functional in nature, and disappear promptly with the subsidence of the other symptoms of the paroxysm. They are generally regarded as manifestations of vascular spasm and this theory is in harmony with their temporary and evanescent nature. In rare cases permanent and often serious consequences ensue. The paralytic and other permanent complications of migraine may appear in various forms as ocular palsies (migraine ophthalmoplegique), organic hemiplegia with aphasia, hemianopsia and optic atrophy. A recurrent facial paralysis has also been ascribed to migraine (facioplegic migraine), and presumably of the same nature and pathogenesis as the ophthalmoplegic of this affection. Migraine, which is usually so harmless, may on occasion be the cause of serious and permanent sequelae. Of great importance from the standpoint of the permanent paralytic sequelae, such as are described in this paper, is the question of the influence of recurring attacks of migraine on an already existing arterial sclerosis. It is very evident that in the presence of cerebral arteriosclerosis, however slight, crises of hemicrania are much more likely to be the cause of vascular accidents, such as thrombosis and hemorrhage, than would be the case in perfectly normal vessels. In the recognition of migraine paralysis the essential points to be considered are: (1) the establishment of a definite clinical history of genuine or idiopathic migraine, and (2) the direct relationship of the paralysis to the migraine paroxysm. As many attacks of hemicrania arise during the day, terminating in a heavy sleep, the presence of paralysis in the morning on awakening would be strong presumptive evidence of an etiologic relationship to migraine. Special emphasis should be placed on the presence of what may be termed "warning symptoms," that is, the recurrence of transient ptosis, diplopia, hemianopsia, hemiparesis, aphasia and jacksonian seizures. A permanent damage to nerve structure resulting from an attack of migraine is fortunately a rare sequel. In this group of accidents, the ocular palsies rank first in importance, because of their relative frequency (migraine ophthalmoplegique). Next in importance among the cranial nerve complications is involvement of the optic nerve resulting from thrombotic occlusion of the central artery of the retina and possibly the retrobulbar neuritis. The graver paralytic complications are naturally those affecting the brain itself, and these are the result of occlusion of the cerebral vessels with consequent encephalomalacia. Such lesions have been observed in the distribution of the sylvian artery causing hemiplegia, hemianesthesia and aphasia, and in the distribution of the posterior cerebral artery when homonymous hemianopsia is the characteristic symptom. While thrombosis is the usual lesion in such cases, it is not improbable that rupture of the vessel also occurs. There are two other groups of cases which should be considered from the standpoint of permanent vascular lesions, namely, the epilepsy which is so often associated with migraine, and the vertigo permanens. Both of these conditions are usually regarded as merely functional substitutions or alternations of the neurosis itself, in other words, as a kind of migraine equivalent. The possibility of a permanent vascular focus resulting from migraine must be considered as a possible etiologic factor in the presence either of epilepsy or of persistent vertigo.

DISCUSSION

Dr. Joseph Collins, New York: There is one feature of these cases that Dr. Hunt has not mentioned, which I consider to be of very great importance, and that is the syphilitic feature. In a series of 100 cases of syphilitic disorder of the nervous system coming in succession, I found two cases of typical migraine, one of them associated with ophthalmoplegia in which the evidence of a syphilitic origin was found in the blood and in the cerebrospinal fluid. I have come now to the conclusion that it is well in the majority of cases of migraine, practically in all cases in which there is paralysis of any sort, to submit them to the laboratory tests.

Dr. L. F. Barker, Baltimore: I can confirm Dr. Hunt's observations of hemianopsia with migraine. I had two cases, one in a lady in middle life. In both of these instances the hemianopsia was temporary, though complete at the time. It passed off and I have not heard from the patients since. In view of what Dr. Hunt has said, it is possible that they may later develop hemianopsia. I have made it a routine practice to make serologic examinations in all neurologic and medical cases. In neither of these cases, however, was a positive Wassermann present, and in my own experience, while migraine and lues do coexist sometimes, it is not common. I have wondered as to the nature of this temporary hemianopsia, and think of a possible temporary lesion in the chiasm and also of a spasm of the occipital artery supplying around the calcarine fissure.

Dr. William G. Spiller, Philadelphia: Some years ago Dr. de Schweinitz sent me a patient who had two attacks of ophthalmoplegia. He had had migraine over many years. His parents had had migraine. Recently I saw a patient who had had two attacks of transitory ophthalmoplegia. One patient died two or three years later of an apoplectic stroke. I have seen two cases of hemianopsia with migraine.

Dr. Alfred Gordon, Philadelphia: Several years ago I had a physician under my charge for periodic attacks of migraine. That man comes from a migraine family. After an attack of migraine I found him hemiplegic on the right side, with astereognosis of the right side and motor aphasia. Not all the symptoms were marked, but they were sufficiently pronounced to observe. He made a complete recovery and is well up to the present time.

Dr. P. C. Knapp, Boston: There is one form of involvement of the cranial nerves of which Dr. Hunt has not spoken, namely, the anesthesias occurring in the distribution of the fifth nerve in connection with attacks of migraine. In regard to the ophthalmoplegic migraines, there are a few interesting points to which Dr. Hunt has not referred. In the great majority of them the ophthalmoplegia is an incidental occurrence. In a very few instances, there is a fairly regular occurrence of the transitory ophthalmoplegia with each attack of the migraine, but it must be borne in mind that even these cases of ophthalmoplegia of short duration occurring as time goes on become more and more permanent. I have seen two cases. Both of the cases have been permanent. One of them I saw a year or two ago, about ten years after the first attack of hemianopsia, coming on with the migraine, and the second one has continued now seven or eight years.

Dr. N. E. Brill, New York: Only recently a nurse in the training school who had had occasional attacks of migraine for a number of years developed a hemiplegia affecting the right arm and leg without any aphasia and without any demonstrable sensory disturbances. Dr. B. Sachs would remember the case, as I asked him to see it at the same time. The hemiplegia disappeared in three days, leaving the girl rather exhausted. She recovered rapidly, and has had an attack of migraine since but no hemiplegia.

Dr. J. Ramsay Hunt, New York: In regard to the pathology of transient and permanent attacks, I myself believe they have the same pathologic basis. They are essentially a vascular spasm. Dr. Collins' suggestion of the possibility of syphilis in migraine is a very important one. As far as possible I have excluded syphilis and regard the cases as essential, or idiopathic, migraine.

Case of Landry's Paralysis: Report on the Histopathological Findings

Dr. E. D. Fisher, New York: The patient, a boy of 15, suddenly became ill, complaining of weakness in the lower extremities. After admission to the hospital, his condition became progressively worse until a complete paraplegia of the lower extremities developed. This was of the flaccid type. Within seven days the upper extremities became involved in the same manner. The muscles of all limbs became atrophied. Reaction of degeneration was present in the lower, and marked quantitative and qualitative electrical changes in the upper extremities and shoulder muscles. There were also partial dissociation of touch, pain and temperature sense in these extremities. Subjective sensory disturbances were a constant accompaniment. Toward the end of his illness, most of the cranial nerves became involved. The bacteriologic examination of the blood and spinal fluid was negative. The cytologic examination of the spinal fluid was negative. A slight rise in temperature marked the entire course of the disease. The patient died of asphyxiation after an illness of six weeks. The necropsy was performed by Dr. John H. Larkin, and specimens of the cord and brain stem and sciatic nerve were prepared by him for examination. The histologic examination revealed changes throughout those tissues. The spinal nerve roots and the sciatic show marked parenchymatous and interstitial changes with an infiltration in the perivascular and perineural lymph spaces of leukocytes, plasma cells and some gitter cells. The cells of the posterior horns at all levels of the cord show a central chromatolysis, especially marked in the cells of Clarke's column. Such type of cell degeneration is also evident throughout the bulb and pons. The cells of the motor neurons show in addition two other types of degeneration, namely, a swelling and coalescence of the Nissl bodies, a tygriosis with eccentric nuclei and staining very deeply and in some places an extensive cell vacuolization. Around these there are to be seen satellite cells which at times dip into the cell body. Their prolongations are visible and are retaining to some extent meshes of chromophilic bodies. The vessels and capillaries are engorged throughout, and at times are seen to burst, producing hemorrhage into the neighboring tissues. Frequently we encounter capillary aneurysms and thrombi. Hemorrhages, rather minute and to all appearance recent, are present at all levels of the cord and brain stem both in the gray and white matter. A marked glia proliferation is a feature throughout. At some levels of the cord an ependymitis of the central canal is present. In a word, we are dealing here with neuritic as well as a cellular involvement, the former being more pronounced. The cell changes of the central chromatolysis type are of a reactionary character owing to remote influences in their neuraxon, while those of the tygriosis type speak for a primary cell involvement as a result of an inflammatory condition around and in the cells. The clinical aspect and the pathologic changes that we find in cases of an acute ascending paralysis of the type of Landry point to an infectious process. Our case would show that both the infectious agent and its toxin are responsible for these changes. Which of the two are predominating is an open question. The predominating type of pathologic changes in Landry's paralysis is that characterized by inflammatory myelitic changes with very slight, if any, nerve changes. For this reason, recent investigators are inclined to regard this disease as poliomyelitis. But in this affection we deal with a distinct etiologic factor and are able to reproduce the characteristic pathologic picture. In Landry's paralysis, divers kinds of cocci and bacilli are found, and the pathologic picture is not uniform. We may conclude that the clinical picture is the criterion of Landry's paralysis, that pathologically there may be a purely cellular, or neuritic only or a neuricellular involvement, and that the time element is no criterion of the disease, since it may last from eight days to eight weeks.

DISCUSSION

Dr. Carl D. Camp, Ann Arbor, Mich.: Some time ago I reported a case of acute unilateral ascending paralysis which came to necropsy in which were found in the peripheral nerves very much the same degenerative changes as are described here. At that time I also noted the abnormality of the anterior horn cells and regarded it as a phenomenon secondary to the changes in the nerve.

Dr. Israel Strauss, New York: Of course we all know cases of Landry's paralysis in which no pathologic lesion is discovered. At first when this disease was described we did not have at our disposal the technic described today. Since those cases were described, other cases have been described, and present distinct clinical features which render it possible that there can be acute ascending paralysis without very much in the way of microscopic lesion.

Meningitis Sympathica

Dr. I. Strauss, New York: Meningitis sympathica is the name given to those changes which occur in the cerebrospinal fluid when an inflammation is present in the neighborhood of the meninges. The pressure of the fluid is greatly increased, and may reach as high as 400 mm. There is an increase in the cellular elements, the cells generally being polynuclear leukocytes. The fluid is sterile. There may be no symptoms of meningitis, but very often there is considerable neck rigidity, and Kernig's symptom is present in varying intensity. One of the most frequent causes of the condition is brain abscess, especially where there has been a previous otitis. It may also be present in patients in whom there is an inflammation of the accessory sinuses or of the structures adjacent to them. We frequently encounter intracranial inflammatory conditions in which there is no evidence of meningeal irritation; but when meningitis sympathica is present it aids us both in the diagnosis and the treatment.

Case of Central and Peripheral Neurofibromatosis (von Recklinghausen's Disease)

Dr. Peter Bassoe and Dr. Frank Nuzum, Chicago: The case was that of a boy 15 years old at death. From the age of 4 years he had attacks once a year, lasting two weeks to three months, of pain in the back near the right scapula. Dragging of left foot was noted after the first attack. At 10 years he had eight eye muscle operations. He had a lump on the left side of the neck noted three years before death, and a pelvic tumor three months before death. Findings on examination suggested basal brain tumor and cord tumor. Several subcutaneous nodules led to a correct clinical diagnosis. Necropsy showed large neurofibromas in both cerebellopontile angles, large tumor of the cauda equina, numerous small tumors on various cranial and spinal nerves, and also tumors on nerve roots, in places invading the cord. There was a large tumor outside the rectum.

Abderhalden Reactions and Defective Mental and Physical States

Dr. S. D. W. Ludlum and Dr. E. P. Corson White, Philadelphia: In the blood of a thymectomized dog we obtained reactions to testis and pancreas, just as had previously been done in patients who had physiologic symptoms of thymectomy. Following this we saw three cases of backwardness in children in which the symptoms were those of lymphatism. These cases reacted to thymus. Results of treatment of these cases with pituitary extract were phenomenal. A girl of 5 years showing gigantism reacted to pituitary. The symptoms were controlled by thyroid extract. We have had ten cases of a hypomaniac state in adults pointing to hyperpituitarism rapidly controlled by the opposite hormone. A case of infantilism which reacted to thymus started to grow when put on pituitary extract.

DISCUSSION

Dr. Henry A. Cotton, Trenton, N. J.: This is the most important problem before the psychiatrist. The question of the influence of the ductless gland or the glands of internal secretion on mental conditions, probably more especially in dementia praecox, seems to be evident today. Following out Cushing's ideas on hypopituitarism, we examined a number of cases. We examined the blood pressure, sugar tolerance, the polyuria, and all of these cases have shown one thing, that there was evidence that the pituitary gland was at fault. There is probably a group of cases in which the thymus is affected, another in which the pituitary is affected and we know the effect the suprarenal and the other glands have. As these studies are developing we can at least look to some definite facts to be gotten out of this work to indicate a proper theory.

AMERICAN GYNECOLOGICAL SOCIETY

Fortieth Annual Meeting, held at White Sulphur Springs, W. Va., May 18-20, 1915

The President, Dr. Thomas J. Watkins, in the Chair

Present Status of Ovarian Transplantation

Dr. Franklin H. Martin, Chicago: Subcutaneous transplantation of ovarian tissue does not increase the risk of operation. In the majority of patients the graft will persist for a time. In my cases it is still present after twenty-seven months, eighteen months, and in three others more than a year. In some patients it appears to functionate, as shown by the apparent development of graafian follicles, by variation in size and tenderness, and by menstruation when the uterus remains. The presence of one ovary in the pelvis does not necessarily interfere with the success of the graft. Those patients in whom ovarian tissue has been grafted seem to have less discomfort from the premature menopause.

What Is the Fate of the Ovaries Left In Situ After Hysterectomy?

Dr. Hiram N. Vineberg, New York: Clinically, it has been found that the freedom from the climacteric syndrome in hysterectomized women, in whom the ovaries have been conserved, is only relative to that which obtains in the same class of women in whom the ovaries have been removed. A generous estimate would be 20 per cent. in favor of the former. To obtain the benefits claimed by the advocates of conservation, the ovaries should be retained at all ages and not limited to those under 40 years, as is done by most of them, inasmuch as it has been shown that of the women who suffer most severely from the artificial menopause, 46 per cent. were only 45 and over. Subsequent disease of the conserved ovary does occur in some cases, the number no doubt being much larger than would be inferred from the records found in the literature. I am of the opinion that the doubtful clinical advantages accruing from retaining the ovaries in hysterectomy are more than counterbalanced by the risk to which the patient is subjected from subsequent disease and adhesions of the conserved ovaries. I would, therefore, not retain the ovaries in any case of hysterectomy, unless I could leave enough of the lower segment of the uterus with its endometrium to insure the function of menstruation, for in my experience the knowledge imparted to the woman that her ovaries have not been removed has but little significance or moral effect when she learns that she will no longer menstruate.

DISCUSSION

Dr. Frank F. Simpson, Pittsburgh: The first instance of transplanted ovarian tissue was one that encouraged us in this line of work. The patient, a young woman of considerable importance in the community, in the thirties, had a perforated appendix, with drainage for general peritonitis. The appendix was removed. Later there were adhesions about both adnexa, which were treated. Six operations were done by leading general surgeons of New York. The young woman was a confirmed invalid. She suffered intensely at the menstrual periods. She, her father and mother insisted on immediate removal of the uterus and adnexa. Every effort was made to relieve the suffering. At the end of a year she suffered as much as she did at the beginning. I removed the pelvic structures. I did not transplant the ovary into the abdominal cavity, thinking it would cause serious trouble, and that disintegration of the ovarian tissue or infection might readily cause serious damage requiring a second abdominal operation. So it occurred to me that to transplant it beneath the skin might be successful. We used the adnexa, transplanted about half of the ovary, it lived, and today it is quite the size it was when transplanted. On a number of occasions I felt the ovary, and I believe I felt the graafian follicles. In that young woman the functional result was good. Instead of being a confirmed invalid and lying in bed, she is about, is vigorous, and practically not harmed at all by the disagreeable phenomena of the precipitated menopause.

Dr. John O. Polak, Brooklyn: I have four unreported cases of transplantation of the ovary. In three of them the entire ovary was transplanted in a pocket in the prevesical space. Two of these have caused no trouble so far as the ovarian graft is concerned. This graft has seemed to have no effect on the symptoms of the menopause. A third has become cystic. She is the only woman of these three who has had relief from the symptoms of the menopause. My fourth case was a graft of the ovary into the cornu of the uterus at the point of excision of the tubes. This patient menstruated for nine months, and then menstruation ceased. She then developed all the symptoms of the postclimacteric with considerable severity, but gradually they have passed away.

Dr. J. Wesley Bovée, Washington, D. C.: The ovary floats freely in the peritoneal cavity. An ovary that becomes encased by adhesions, and not necessarily by marked infection, begins to undergo sclerocystic degeneration. When we transplant these ovaries we cover them entirely with tissue, and they will undergo degeneration. I do not believe that the results are good or will be good so long as this plan is followed. When we resort to transplantation of ovarian tissue, it must be done in such a way as to give freedom to such tissue.

Dr. Hiram N. Vineberg. New York City: I have had two cases of autotransplantation of the ovary, taking a small wedge-shaped piece of the ovary and inserting it into the lower abdominal wound, leaving it in between the fat and the skin. In one of these cases the operation was done nine months ago and in the other about six months ago. There has been absolutely no difference in the healing of the wound. So far as one can tell from frequent examination since then, one could not tell that a transplantation had been done.

Dr. John J. Clark, Philadelphia: I have endeavored to expose the cortex, open the ovary, pull it open as one would a kidney, and allow the vascular portion to come into direct contact with the peritoneum, which I have utilized, and not the subcuticular tissue, as Dr. Simpson has done. Thus far my experience has not been particularly satisfactory.

Dr. Herman J. Boldt, New York: In view of the fact that there are undoubtedly instances in which the symptoms of the menopause are at least ameliorated if a seemingly normal gland is conserved either by ordinary conservation or by transplantation, I want to continue that line of work. On the other hand, I can only say that in those instances in which conservatism has been practiced, I have had the same disagreeable features to contend with that others have had. I recall two instances in which it became necessary for me to reopen the abdomen and to remove an ovarian cyst from the ovary which had been retained. I cannot recall any instance in which the removal of cysts has been more difficult than in those two cases. However, as I have said, there are instances in which the symptoms of the menopause are at least ameliorated and where they are entirely absent.

Dr. J. Riddle Goffe, New York: About twelve years ago I made my first adventure into this field of work. It was on a young woman whose tubes were absolutely destroyed by disease. She was anxious to have children. I removed both tubes and one ovary; then I slit open widely the whole fundus of the uterus, being careful to preserve the mucosa of the salpinx in my obliterating operation, and to retain as far as possible the lymphatics and the arterial nutrition of the ovary. Without splitting the ovary, I turned it right around and hung it free in the uterine cavity. The patient had a slight discharge of blood at the regular time of menstruation once; then she escaped from my observation, and I have not been able to get any further information in regard to the case.

Dr. Joseph Brettauer, New York: Each case for ovarian transplantation ought to be individualized. To some women of a nervous temperament or who are neurasthenic, the removal of the ovaries is a more serious matter than it is to other women who are not so constituted.

Dr. Willis E. Ford, Utica: I am pessimistic about leaving parts of ovaries. My experience has prejudiced me against it.

Dr. Philander A. Harris, Paterson, N. J.: It has been my rule in removing the uterus to leave an ovary or both ovaries, if possible. I leave all the tissues that are healthy. I was rather encouraged when I heard Dr. Goffe speak of having placed a piece of ovary in the uterus, but if the woman became pregnant, would it not cause a rupture of the uterus?

Dr. Herman J. Boldt: Are there cases in which, after an ovary has been left and the oviducts removed, the woman has subsequently become pregnant?

Dr. Bovée: There are many such cases on record.

Nitrous Oxid in Labor

Dr. N. Sproat Heaney, Chicago: (See abstract of paper by Dr. F. W. Lynch in The Journal, April 3, p. 1187.)

DISCUSSION

Dr. John O. Polak, Brooklyn: Is it possible to continue nitrous oxid gas from the very beginning of labor as an analgesic method? About what would be the approximate cost of conducting a twelve to twenty-four-hour first stage with it, and how much personal attention would the obstetrician have to give in the management of the case?

Dr. Willis E. Ford, Utica: Was there any cyanosis in the children, and is there more cyanosis from the use of gas than from ether?

Dr. Louis Frank, Louisville: I have used nitrous oxid gas as the anesthetic of choice in my surgical work for almost three years, including three cases of cesarean section. The administration of nitrous oxid gas and oxygen for analgesic purposes requires the services of an expert. It is the most dangerous of all anesthetics in unskilled hands, while in skilled hands it is the safest. The cost of the gas is lessened materially where large tanks are used and the gas is manufactured in the hospital.

Dr. Hiram N. Vineberg, New York: In one or two instances I attempted to do a plastic operation under nitrous oxid and oxygen, but the blood was so black that the field of operation was obscured. We had to stop. I do not know whether it was improperly administered or not.

Dr. N. S. Heaney: During the latter part of the first stage and second stage we can give gas for 60 cents an hour. The amount of oxygen varies with each patient. It depends how quickly the woman passes into cyanosis and how much oxygen one should give. The less the amount of gas given the better. With the nose piece the cyanosis in the infant is less marked. It is hard to determine what the effect of any method is, provided the baby does not require artificial respiration. If it is blue it cries immediately. It is very gratifying in cesarean sections to have the child cry at once. You can then dismiss the child from your mind and attend to the mother, a thing which you are not able to do always under ether anesthesia in cesarean section.

The Management of the Placental Stage of Labor, with Special Reference to Retained and Adherent Placenta

Dr. John O. Polak, Brooklyn: The placenta will separate spontaneously if the normal mechanism is allowed to obtain. Any manipulation of the uterus before the clinical evidences of separation are apparent will disturb this normal mechanism. Postpartum hemorrhage is best guarded against by the observance of the physiologic processes. Partial detachment, the result of manipulation, predisposes to bleeding. The normal mechanism of placental delivery is that described by Schultze. The Duncan mechanism occurs only in low implantations of the placenta or when manipulation has been untimely and vigorous. The placenta may be retained in the uterus for hours or days without danger to the patient, provided it is attached or completely detached, which insures that the bleeding will be negligible. Asepsis is dependent on the penetration of the uterus by the hand or instrument to infected passages, and not on the retention of the placenta. Manual extraction is admissible only in partial separation with hemorrhage. In retention of the placenta without hemorrhage, the cord should be cut off close to the cervix and the case watched until the time of separation is apparent, when the placenta may be expressed by Credé while the patient is under surgical anesthesia. Invasion of the uterus via the vagina is fraught with danger from infection, and on exploration, should the placenta not be found presenting at the internal os, infrapelvic delivery should be abandoned and delivery accomplished through sterile avenues by suprapubic extraperitoneal hysterotomy. When the adhesion is so great that its removal entails the digging out of the placenta piecemeal, excision of the placental site or hysterectomy should be the choice.

DISCUSSION

Dr. Walter P. Manton, Detroit: Implantation of the placenta is, as a rule, a good deal lower than is usually supposed. A number of years ago I found that in several hundred consecutive cases the implantation was a good deal lower than what is stated in the textbooks. The implantation is apt to be lateral rather than frontal or parietal; therefore I do not believe that the Schultze method of delivery of the placenta is the normal one, but that the Duncan method is.

Dr. George Tucker Harrison, Charlottesville, Va.: In cases in which the placenta is detached, the Duncan method is the one that should be employed. It is wrong to exercise compression as soon as the child is born. Let it alone.

Dr. Philander A. Harris, Paterson, N. J.: A placenta with the cord hanging from it was allowed to remain experimentally. It was all absorbed. We kept the patient in the hospital for weeks and weeks, and after absorption the uterus returned to its normal condition.

Primary Cancer of the Female Urethra: Plastic Work and Late Results

Dr. H. S. Crossen, St. Louis: To determine the proportion of cases of cancer cured by operation, I have tabulated the operative cases found in a cursory examination of the literanation suggested basal brain tumor and cord tumor. Several subcutaneous nodules led to a correct clinical diagnosis. Necropsy showed large neurofibromas in both cerebellopontile angles, large tumor of the cauda equina, numerous small tumors on various cranial and spinal nerves, and also tumors on nerve roots, in places invading the cord. There was a large tumor outside the rectum.

Abderhalden Reactions and Defective Mental and Physical States

Dr. S. D. W. Ludlum and Dr. E. P. Corson White, Philadelphia: In the blood of a thymectomized dog we obtained reactions to testis and pancreas, just as had previously been done in patients who had physiologic symptoms of thymectomy. Following this we saw three cases of backwardness in children in which the symptoms were those of lymphatism. These cases reacted to thymus. Results of treatment of these cases with pituitary extract were phenomenal. A girl of 5 years showing gigantism reacted to pituitary. The symptoms were controlled by thyroid extract. We have had ten cases of a hypomaniac state in adults pointing to hyperpituitarism rapidly controlled by the opposite hormone. A case of infantilism which reacted to thymus started to grow when put on pituitary extract.

DISCUSSION

Dr. Henry A. Cotton, Trenton, N. J.: This is the most important problem before the psychiatrist. The question of the influence of the ductless gland or the glands of internal secretion on mental conditions, probably more especially in dementia praecox, seems to be evident today. Following out Cushing's ideas on hypopituitarism, we examined a number of cases. We examined the blood pressure, sugar tolerance, the polyuria, and all of these cases have shown one thing, that there was evidence that the pituitary gland was at fault. There is probably a group of cases in which the thymus is affected, another in which the pituitary is affected and we know the effect the suprarenal and the other glands have. As these studies are developing we can at least look to some definite facts to be gotten out of this work to indicate a proper theory.

AMERICAN GYNECOLOGICAL SOCIETY

Fortieth Annual Meeting, held at White Sulphur Springs, W. Va., May 18-20, 1915

The President, Dr. Thomas J. Watkins, in the Chair

Present Status of Ovarian Transplantation

Dr. Franklin H. Martin, Chicago: Subcutaneous transplantation of ovarian tissue does not increase the risk of operation. In the majority of patients the graft will persist for a time. In my cases it is still present after twenty-seven months, eighteen months, and in three others more than a year. In some patients it appears to functionate, as shown by the apparent development of graafian follicles, by variation in size and tenderness, and by menstruation when the uterus remains. The presence of one ovary in the pelvis does not necessarily interfere with the success of the graft. Those patients in whom ovarian tissue has been grafted seem to have less discomfort from the premature menopause.

What Is the Fate of the Ovaries Left In Situ After Hysterectomy?

Dr. Hiram N. Vineberg, New York: Clinically, it has been found that the freedom from the climacteric syndrome in hysterectomized women, in whom the ovaries have been conserved, is only relative to that which obtains in the same class of women in whom the ovaries have been removed. A generous estimate would be 20 per cent. in favor of the former. To obtain the benefits claimed by the advocates of conservation, the ovaries should be retained at all ages and not limited to those under 40 years, as is done by most of them, inasmuch as it has been shown that of the women who suffer most severely from the artificial menopause, 46 per cent. were only 45 and over. Subsequent disease of the conserved ovary does occur in some cases, the number no doubt being much larger than would be inferred from the records found in the literature. I am of the opinion that the doubtful clinical advantages accruing from retaining the ovaries in hysterectomy are more than counterbalanced by the risk to which the patient is subjected from subsequent disease and adhesions of the conserved ovaries. I would, therefore, not retain the ovaries in any case of hysterectomy, unless I could leave enough of the lower segment of the uterus with its endometrium to insure the function of menstruation, for in my experience the knowledge imparted to the woman that her ovaries have not been removed has but little significance or moral effect when she learns that she will no longer menstruate.

DISCUSSION

Dr. Frank F. Simpson, Pittsburgh: The first instance of transplanted ovarian tissue was one that encouraged us in this line of work. The patient, a young woman of considerable importance in the community, in the thirties, had a perforated appendix, with drainage for general peritonitis. The appendix was removed. Later there were adhesions about both adnexa, which were treated. Six operations were done by leading general surgeons of New York. The young woman was a confirmed invalid. She suffered intensely at the menstrual periods. She, her father and mother insisted on immediate removal of the uterus and adnexa. Every effort was made to relieve the suffering. At the end of a year she suffered as much as she did at the beginning. I removed the pelvic structures. I did not transplant the ovary into the abdominal cavity, thinking it would cause serious trouble, and that disintegration of the ovarian tissue or infection might readily cause serious damage requiring a second abdominal operation. So it occurred to me that to transplant it beneath the skin might be successful. We used the adnexa, transplanted about half of the ovary, it lived, and today it is quite the size it was when transplanted. On a number of occasions I felt the ovary, and I believe I felt the graafian follicles. In that young woman the functional result was good. Instead of being a confirmed invalid and lying in bed, she is about, is vigorous, and practically not harmed at all by the disagreeable phenomena of the precipitated menopause.

Dr. John O. Polak, Brooklyn: I have four unreported cases of transplantation of the ovary. In three of them the entire ovary was transplanted in a pocket in the prevesical space. Two of these have caused no trouble so far as the ovarian graft is concerned. This graft has seemed to have no effect on the symptoms of the menopause. A third has become cystic. She is the only woman of these three who has had relief from the symptoms of the menopause. My fourth case was a graft of the ovary into the cornu of the uterus at the point of excision of the tubes. This patient menstruated for nine months, and then menstruation ceased. She then developed all the symptoms of the postclimacteric with considerable severity, but gradually they have passed away.

Dr. J. Wesley Bovée, Washington, D. C.: The ovary floats freely in the peritoneal cavity. An ovary that becomes encased by adhesions, and not necessarily by marked infection, begins to undergo sclerocystic degeneration. When we transplant these ovaries we cover them entirely with tissue, and they will undergo degeneration. I do not believe that the results are good or will be good so long as this plan is followed. When we resort to transplantation of ovarian tissue, it must be done in such a way as to give freedom to such tissue.

Dr. Hiram N. Vineberg, New York City: I have had two cases of autotransplantation of the ovary, taking a small wedge-shaped piece of the ovary and inserting it into the lower abdominal wound, leaving it in between the fat and the skin. In one of these cases the operation was done nine months ago and in the other about six months ago. There has been absolutely no difference in the healing of the wound. So far as one can tell from frequent examination since then, one could not tell that a transplantation had been done.

Dr. John J. Clark, Philadelphia: I have endeavored to expose the cortex, open the ovary, pull it open as one would a kidney, and allow the vascular portion to come into direct contact with the peritoneum, which I have utilized, and not the subcuticular tissue, as Dr. Simpson has done. Thus far my experience has not been particularly satisfactory.

Dr. Herman J. Boldt, New York: In view of the fact that there are undoubtedly instances in which the symptoms of the menopause are at least ameliorated if a seemingly normal gland is conserved either by ordinary conservation or by transplantation, I want to continue that line of work. On the other hand, I can only say that in those instances in which conservatism has been practiced, I have had the same disagreeable features to contend with that others have had. I recall two instances in which it became necessary for me to reopen the abdomen and to remove an ovarian cyst from the ovary which had been retained. I cannot recall any instance in which the removal of cysts has been more difficult than in those two cases. However, as I have said, there are instances in which the symptoms of the menopause are at least ameliorated and where they are entirely absent.

Dr. J. Riddle Goffe, New York: About twelve years ago I made my first adventure into this field of work. It was on a young woman whose tubes were absolutely destroyed by disease. She was anxious to have children. I removed both tubes and one ovary; then I slit open widely the whole fundus of the uterus, being careful to preserve the mucosa of the salpinx in my obliterating operation, and to retain as far as possible the lymphatics and the arterial nutrition of the ovary. Without splitting the ovary, I turned it right around and hung it free in the uterine cavity. Dr. Joseph Brettauer, New York: Each case for ovarian transplantation ought to be individualized. To some women of a nervous temperament or who are neurasthenic, the removal of the ovaries is a more serious matter than it is to other women who are not so constituted.

Dr. Willis E. Ford, Utica: I am pessimistic about leaving parts of ovaries. My experience has prejudiced me against it.

Dr. Philander A. Harris, Paterson, N. J.: It has been my rule in removing the uterus to leave an ovary or both ovaries, if possible. I leave all the tissues that are healthy. I was rather encouraged when I heard Dr. Goffe speak of having placed a piece of ovary in the uterus, but if the woman became pregnant, would it not cause a rupture of the uterus?

Dr. Herman J. Boldt: Are there cases in which, after an ovary has been left and the oviducts removed, the woman has subsequently become pregnant?

Dr. Bovée: There are many such cases on record.

Nitrous Oxid in Labor

Dr. N. Sproat Heaney, Chicago: (See abstract of paper by Dr. F. W. Lynch in The Journal, April 3, p. 1187.)

DISCUSSION

Dr. John O. Polak, Brooklyn: Is it possible to continue nitrous oxid gas from the very beginning of labor as an analgesic method? About what would be the approximate cost of conducting a twelve to twenty-four-hour first stage with it, and how much personal attention would the obstetrician have to give in the management of the case?

Dr. Willis E. Ford, Utica: Was there any cyanosis in the children, and is there more cyanosis from the use of gas than from ether?

Dr. Louis Frank, Louisville: I have used nitrous oxid gas as the anesthetic of choice in my surgical work for almost three years, including three cases of cesarean section. The administration of nitrous oxid gas and oxygen for analgesic purposes requires the services of an expert. It is the most dangerous of all anesthetics in unskilled hands, while in skilled hands it is the safest. The cost of the gas is lessened materially where large tanks are used and the gas is manufactured in the hospital.

Dr. Hiram N. Vineberg, New York: In one or two instances I attempted to do a plastic operation under nitrous oxid and oxygen, but the blood was so black that the field of operation was obscured. We had to stop. I do not know whether it was improperly administered or not.

Dr. N. S. Heaney: During the latter part of the first stage and second stage we can give gas for 60 cents an hour. The amount of oxygen varies with each patient. It depends how quickly the woman passes into cyanosis and how much oxygen one should give. The less the amount of gas given the better. With the nose piece the cyanosis in the infant is less marked. It is hard to determine what the effect of any method is, provided the baby does not require artificial respiration. If it is blue it cries immediately. It is very gratifying in cesarean sections to have the child cry at once. You can then dismiss the child from your mind and attend to the mother, a thing which you are not able to do always under ether anesthesia in cesarean section.

The Management of the Placental Stage of Labor, with Special Reference to Retained and Adherent Placenta

Dr. John O. Polak, Brooklyn: The placenta will separate spontaneously if the normal mechanism is allowed to obtain. Any manipulation of the uterus before the clinical evidences of separation are apparent will disturb this normal mechanism. Postpartum hemorrhage is best guarded against by the observance of the physiologic processes. Partial detachment, the result of manipulation, predisposes to bleeding. The normal mechanism of placental delivery is that described by Schultze. The Duncan mechanism occurs only in low implantations of the placenta or when manipulation has been untimely and vigorous. The placenta may be retained in the uterus for hours or days without danger to the patient, provided it is attached or completely detached, which insures that the bleeding will be negligible. Asepsis is dependent on the penetration of the uterus by the hand or instrument to infected passages, and not on the retention of the placenta. Manual extraction is admissible only in partial separation with hemorrhage. In retention of the placenta without hemorrhage, the cord should be cut off close to the cervix and the case watched until the time of separation is apparent, when the placenta may be expressed by Credé while the patient is under surgical anesthesia. Invasion of the uterus via the vagina is fraught with danger from infection, and on exploration, should the placenta not be found presenting at the internal os, infrapelvic delivery should be abandoned and delivery accomplished through sterile avenues by suprapubic extraperitoneal hysterotomy. When the adhesion is so great that its removal entails the digging out of the placenta piecemeal, excision of the placental site or hysterectomy should be the choice.

DISCUSSION

Dr. Walter P. Manton, Detroit: Implantation of the placenta is, as a rule, a good deal lower than is usually supposed. A number of years ago I found that in several hundred consecutive cases the implantation was a good deal lower than what is stated in the textbooks. The implantation is apt to be lateral rather than frontal or parietal; therefore I do not believe that the Schultze method of delivery of the placenta is the normal one, but that the Duncan method is.

Dr. George Tucker Harrison, Charlottesville, Va.: In cases in which the placenta is detached, the Duncan method is the one that should be employed. It is wrong to exercise compression as soon as the child is born. Let it alone.

Dr. Philander A. Harris, Paterson, N. J.: A placenta with the cord hanging from it was allowed to remain experimentally. It was all absorbed. We kept the patient in the hospital for weeks and weeks, and after absorption the uterus returned to its normal condition.

Primary Cancer of the Female Urethra: Plastic Work and Late Results

Dr. H. S. Crossen, St. Louis: To determine the proportion of cases of cancer cured by operation, I have tabulated the operative cases found in a cursory examination of the literature as follows: cases subjected to radical operation, 25; cured (three years), 8; probable cures (two years), 3; recurrences, known, 8; results not known, 6. Of the treated cases, about half were cured. This is a very encouraging showing, considering the fact that lymphatic metastases take place directly in the deep glands within the pelvis. On account of the direction of the lymphatic drainage, the first metastases made recurrence certain, for the affected glands were beyond reach. Some of the operations were not very extensive, the operators removing only a half or two-thirds of the urethra. The large proportion of cures was probably due to the fact that in the urethra an area of irritation causes symptoms very early, and thus leads to investigation in diagnosis and radical treatment while the disease is still in a comparatively early stage.

DISCUSSION

Dr. Lewis S. McMurtry, Louisville: The chances for a radical operation being successful are endangered by the natural delay in making a diagnosis. I venture to say that nearly all cases reported have been primarily operated on as urethral caruncle, and the malignant character of the growth has been lost sight of until the patient has been under treatment for some time, and then failure of this treatment and extension of the growth have impressed the surgeon with its true character. If these cases were seen early and diagnosed promptly, the results from complete excision would be much better.

Dr. Frederick J. Taussig, St. Louis: Three months ago I removed a small nodule from the urethra of a woman, aged 53, and our pathologist examined it a long time before he made up his mind it was not malignant. The epithelial proliferations in the urethra closely simulate early cancer; probably a certain number of these cases that have been reported as cures were not really cancers.

Dr. Joseph Brettauer, New York: I have had one case of primary carcinoma of the urethra. It is exceedingly difficult, if not impossible, to differentiate between early carcinoma of the urethra and urethral caruncle. It is more guesswork than anything else.

Dr. Hiram N. Vineberg, New York: In one of my cases, the specimen was examined by two good pathologists, and both made a diagnosis of carcinoma. The woman is still free from recurrence, ten years after the operation.

Dr. Willis E. Ford, Utica: In a case in which the growth was as large as a walnut and obstructing the passage of urine, I removed the urethra to such an extent that I thought I left but little of it. The patient got retention of urine. The growth returned within six or eight months. Since that time I have seen half a dozen cases, and with the exception of primary cancer of the clitoris, I think it is the most rapidly fatal of all cancers.

Prolapsus of Uterus

Dr. Herman J. Boldt, New York: Before deciding on a particular operation, it is well to consider whether future offspring is desired by the patient or not. A simple vaginal hysterectomy for prolapse of the uterus should have no place in our work, since by it a vaginal descensus cannot be cured. I know of no operation which answers an equally good purpose as a ventral suspension by the round ligament *a là* Gilliam, combined with a plastic operation on the pelvic floor, but not with too much narrowing of the vaginal canal. If properly done, a permanent cure will result in 90 per cent. of the cases unless a subsequent pregnancy should undo the result of the operation. Patients who have a marked descensus, or partial or complete prolapsus, in whom no further offspring is expected, may be treated by a vaginal operation with the expectation of getting a good result. I prefer the radical vaginal fixation. The technic must necessarily vary with the individual case. In patients who have complete procidentia of the uterus and vagina, and where no further use of the vaginal canal is to be made, we can do a total extirpation of the uterus and vagina, columnizing the vaginal tract by circular sutures, an operation that is comparatively simple, and an absolute guarantee as to permanent results.

2 *Development of Thymus in Pig. J. A. Badertscher. Ithaca, N. Y.
3 Premature Obliteration of Sutures in Human Skull. L. Bolk, Amsterdam.

1. **Origin of Posterior Lymph Heart.**—The evidence found by West from the study of injected embryos indicates that the lymphatic plexus which later enters into the formation of the posterior lymph heart, arises by the confluence of independent mesenchymal spaces which connect secondarily with the veins, that these spaces are bounded at first by mesenchymal cells which later become flattened to form an endothelium, and that both in the endothelial lymphatic walls and the adjacent mesenchyme an active hemopoesis, the products of which reach the general circulation via the lymphatic plexus, is taking place.

2. **Development of Thymus.**—The lymphocytes first present in the thymus Badertscher found are all large lymphocytes and have migrated into it from the mesenchyme. The numerous small round cells of the thymus are formed by the repeated division of the large lymphocytes which thus become small, and also by their own proliferation. Judging from the source and structure of the small round cells they are small lymphocytes and are identical with the small lymphocytes of the blood. The thymus, therefore, may well be considered as a source of some of the small lymphocytes found in the circulating blood. The reticulum of the thymus is of epithelial origin and is formed passively by its meshes becoming filled with lymphocytes which further separate the nodal nuclei and thus greatly attenuate the protoplasmic processes of the syncytium. The Hassall's corpuscles are of epithelial origin. The free red blood cells and eosinophil cells found in both interlobular septa and the thymic lobules are derived from lymphocytes in situ.

Whether or not any of the erythrocytes formed in the thymus enter the circulating blood, Badertscher says, is difficult to determine in fixed material. Some of the free erythrocytes undoubtedly undergo degeneration and the products of disintegration of those existing in the form of eosinophil granules are taken up by the lymphocytes which thus become transformed into eosinophil leukocytes. The histogenesis of the thymus is divided into epochs each of which is characterized by more or less distinct development features. They are: 1. The purely epithelial epoch which extends from its origin as an outpocketing from the third pharyngeal pouch and the formation of the cervical vesicle to the appearance of the first lymphocytes in the thymus. 2. The epoch of lymphocyte infiltration and lymphocyte proliferation and the formation of the reticulum. 3. The epoch of the formation of red blood cells and the development of granular cells.

7. Investigation of Potency of Tincture of Aconite.—Robinson's experience with tincture of aconite as a means of lowering the pulse rate was obtained in an attempt to influence the tachycardia of exophthalmic goiter. A study of this condition was undertaken on the hypothesis that the tachycardia resulted from a lack of balance between the cardiac accelerators and the vagi and that if the so-called vagus tone could be increased, the cardiac rate would diminish. The tincture of aconite was administered in five cases of exophthalmic goiter, three of which were moderately severe, while two were mild. All of the patients had enlarged thyroids and tremor, while exophthalmos was very marked in two, moderate in two and absent in one case. The pulse rate after several days' rest in bed ranged from 110 to 120 beats per minute in one case, from 90 to 100 in two, and from 85 to 95 in two cases. In order to ascertain any effect the tincture of aconite might have on the heart in these cases, the pulse rate was studied under various conditions, both before and during the administration of the drug. These conditions consisted of rest in bed immediately after a constant amount of moderate exercise, and after administration of full doses of atropin. It was found that very large doses of the tincture of aconite produced no subjective symptoms and no slowing of the heart rate. Doses of 10 c.c. (approximately 150 drops) were given six times a day. An attempt to augment the action of aconite by physostigmin was not successful.

Although the chemical assay showed that the tincture used did not fulfil the Pharmacopeial requirements as regards its aconitin content, the discrepancy was not sufficient to account for the impotency of the drug. The physiologic assay showed that the minimal lethal dose for guinea-pigs of a substance giving the chemical tests for aconitin contained in the tincture was at least forty-five times as large as that of crystalline aconitin, and that the alcohol of the tincture apparently played no rôle in diminishing the toxicity of the solution by decomposing the aconitin. This substance in the tincture can hardly, therefore, be considered identical with crystalline aconitin. Robinson believes that these facts emphasize the necessity of physiologic standardization of the tincture of aconite, which is not now required by the Pharmacopeia. Evidence was obtained that the maximal doses of the tincture of aconite rendered the ventricles more liable to spontaneous contractions, apparently increasing their irritability.

8. Nuclear Digestion and Uric Acid Excretion in Occlusion of Pancreatic Duct.—The results of Atchley's experiment prove that in the human being the digestion of nuclear material, the purin metabolism and the uric acid formation do not depend on the presence of the pancreatic secretion in the intestinal canal. This finding, together with the negative result of the test in this case, and in many other reported cases, Atchley says, definitely points out the worthlessness of the Schmidt nuclear test for pancreatic function.

9. Relation of Secondary Hypertrophic Osteo-Arthropathy to Simple Clubfingers.—Hypertrophic osteo-arthropathy is considered by Locke to be always a secondary disease. Among the primary diseases, pulmonary tuberculosis is probably the most important though rarely inducing the extreme degree of bone and joint changes seen with bronchiectasis. There is a very definite correspondence between the characteristic clinical course of the disease and the process in the bones. During the periods of exacerbation in the primary disease, the pain, tenderness and swelling in the soft parts are not only increased, but the process in the bones is also more active. On the other hand, during the quiescent periods associated with cure or relief of the condition responsible for the bone and joint changes, the process in the bones is stationary and in rare instances actual resorption takes place. The new subperiosteal bone, which is at first sharply marked off from the old shaft, later becomes (usually after a period of some years) a more compact, dense layer, closely fused with the underlying old bone. In the late stages of the most progressive type of cases there is evidence of wide-spread halisteresis in the affected long bones. Occasionally the process in the bones and joints once established may progress even after actual cure of the primary disease.

The ungual phalanges as a rule show proliferative changes. They consist mainly in an irregular burr-like expansion of the distal half. More rarely small osteophytes are found at the proximal ends near the line of the joint cartilage. The epiphyses of the affected long bones are to some extent always involved, but the new osseous tissue is much more irregular in in outline and the ossification is less complete. The proliferation in the long bones in advanced cases is more general than has been recognized, often affecting nearly the entire skeleton. Changes in the joints are a constant and important feature of the disease. While the early changes are confined largely to the periarticular tissues, in the later stages, erosion of the cartilage, lipping about the joint, and even a moderate degree of ankylosis are common lesions. A considerable percentage of cases of so-called hippocratic fingers show by means of roentgenogram early proliferative changes in the periosteum of some of the long bones of the forearms and lower legs of exactly the same type as seen in hypertrophic osteo-arthropathy. Locke says that simple clubbing of the fingers and secondary hypertrophic osteo-arthropathy should be considered as identical, the former representing an early stage of the latter.

12. Factors of Coagulation in Primary Pernicious Anemia.—The studies made by Drinker and Hurwitz seem to emphasize the following points: 1. Prothrombin is diminished slightly in all cases of pernicious anemia. 2. This diminution is not great and is unimportant if active regeneration is in progress 3. Antithrombin and fibrinogen are normal even in the presence of very low cell counts. 4. In one case in which there has been pronounced diminution in prothrombin, platelet counts have been strikingly low, and the picture throughout has been that of fairly complete aplasia.

14. Mercury Nephritis.—In the case of mercuric poisoning reported by Foster the patient lived forty-one days. The history presents some interesting departures from the common course of events in cases of this sort in which the duration of life is brief. Anuria was at no time a symptom, and when the amount of urine fell below normal this was adequately accounted for by a low ingestion of fluids. When the water intake was forced there was apparently a normal response in output. In contrast again with the usual picture are the convulsive seizures, muscular twitching and the toxic psychosis. Of those symptoms which are associated with uremia, there were observed in this case, besides the evidences of renal disease, epileptiform convulsions, muscular twitching and a psychosis of the usual toxic type. The necropsy disclosed, besides an eroded condition of the lower bowel and degenerative changes in the liver, a remarkable nephritis which was studied with care from many sections. The lesions found were those usually encountered in the kidney in cases of bichlorid (mercuric chlorid) poisoning.

15. Oculocardiac Reflex.—The material for Levine's study consisted of eight cases of tabes dorsalis, one case of taboparesis, five cases of syphilis which were nontabetic, nine cases of chronic endocarditis (having a normal rhythm), one case of chronic endocarditis with auricular fibrillation, five cases of lobar pneumonia, and one case of diabetes mellitus. The five nontabetic syphilitics included two cases of syphilis of the cerebrospinal meninges, one of syphilitic myelitis, one of syphilis of the heart, and one patient who has been observed during the secondary stage and who now suggests signs of early tabes. Levine states that the oculocardiac reflex (inhibition of the heart produced by ocular pressure) is a normal but variable reflex. Some individuals normally have a more active oculocardiac reflex than others, just as some have more active tendon and superficial reflexes. In fact, when the reflex is considered absent there is often a slight inhibition of the heart. The reflex was found to be generally absent in tabes dorsalis. The only tabetic who had a moderate oculocardiac reflex, had no pupillary reaction to light whatever. In tabetics there was no difference between the effects of pressure on the two eyes. In nontabetics there was a distinct difference. The right reflex had a slightly greater effect on auricular contraction.

In Levine's opinion ocular pressure affords a simple and safe method of obtaining reflex vagus inhibition of the heart. Inhibition of the heart by the oculocardiac reflex is much more profound and more frequently obtained than by pressure over the vagus nerves. The oculocardiac reflex is generally absent in tabes dorsalis, present in pneumonia, syphilis (nontabetic) and chronic valvular disease. The reflex was absent in one case of diabetes mellitus and also in one case of auricular fibrillation before digitalis treatment. It was present after digitalis was given. Right ocular pressure has a slightly greater effect on the rate of the heart than left. It may stop the heart for a long period of time, relatively speaking, the *P* waves are sometimes diminished in size and may become iso-electric. Occasionally the auriculoventricular interval is lengthened. Left ocular pressure has a much greater effect on the conduction mechanism of the heart than right. It may lengthen auriculoventricular conduction, cause partial heart block and result, possibly, in automatic ventricular rhythm. On two occasions inverted *P* waves were seen. The height of the *R* waves is sometimes increased, at other times diminished. Ectopic ventricular beats were twice observed. The *P* waves are often diminished in size, but occasionally are increased. Escaped ventricular beats were seen both during right and left ocular pressure. Pain, flushing of the face, and apnea during ocular pressure, are much less pronounced in tabetics than in nontabetics. The effects on the rate and on the rhythm of the heart produced by ocular pressures are not constant, differing in different individuals and in the same individual from time to time. The duration and the degree of pressure play an important part in the degree of inhibition.

16. **Coarse Auricular Fibrillation in Man.**—A case of continuous irregularity is reported by Hewlett and Wilson in which the venous curves were characterized by numerous very rapid and irregular waves produced by auricular activity. These waves bore no definite relationship to the auricular fluctuations of the galvanometer string. The authors believe the condition to be one of unusually coarse auricular fibrillation.

31 Metabolic Influence of Chlorids on Certain Dermatoses. M. L. Ravitch and S. A. Steinberg, Louisville.

29. **Treatment of Hyperkeratotic Eczema of Palms and Soles.**—The hands are exposed to injurious influences, such as rough weather, water, cleansing agents, chemical solutions and various traumatisms, and the feet are commonly encased in ill-fitting and deforming shoes, which produce callosities and breaking down of the arch, thereby increasing sweating of the soles and resulting in maceration of the keratotic, thick epithelium. In no other type of chronic eczema is local treatment more efficacious and more satisfactory says Montgomery and Culver than in hyperkeratotic eczema of the palms and soles.

Locally a plaster mull may be employed, containing 5 per cent. salicylic acid in soap plaster:

℞	Acidi salicylici	5 per cent.
	Emplastri saponis (Beiersdorf)	95 per cent.

This is applied on the fingers and covered with zinc oxid adhesive plaster, so as to intensify its action. This is changed once in twenty-four hours. Under its use the hard, concrete-like hyperkeratosis of the fingers melt down, and the skin becomes smooth and supple. This plaster can not be applied to the feet as it would crumple up in walking, but an ointment may be prepared of about 12 per cent. salicylic acid in equal parts of lanolin and petrolatum, as follows:

℞	Acidi salicylici	8.00 gm.
	Lanolin,	
	Petrolatum	āā 32.00 gm.
M.		

This is applied in the morning, so that in walking it will be massaged into the skin. A few days later, when the patient is able to resume work, an ointment composed of one part of mercury in ninety-nine parts of simple ointment is used.

℞	Hydrarg. salicylatis	1.00 gm.
	Ung. simplicis	99.00 gm.
M.		

A salve composed of 6 per cent. each of red oxid of mercury and camphor and 12 per cent. of white lead, in an ointment base composed of equal parts of lanolin and petrolatum, may be used as follows:

℞	Hydrarg. oxidi rubri,	
	Camphorae	āā 4.00 gm.
	Plumbi carbonatis	4.00 gm.
	Lanolin,	
	Petrolatum	āā 32.00 gm.
M.	Sig.: Well rubbed in, twice a day.	

In one case cited by Montgomery and Culver, after five weeks the daily applications were changed from the above to a lotion consisting of:

℞	Kali caustic	1.50 gm.
	Glycerin	50.00 gm.
	Spts. vini rect	50.00 gm.
	Aquae rosae	ad 150.00 gm.
M.	Sig.: Local use, twice a day, before using a salve; and a salve consisting of:	
℞	Hydrarg salicylatis	0.30 gm.
	Paraffin	5.00 gm.
	Petrolatum alb.	25.00 gm.
M.	Sig.: Rub in twice a day.	

Another patient sought treatment on account of a hyperkeratotic eczema of the fingers and right palm. He also had hyperidrosis, accompanied with light red erythema of both palms. A lotion was prescribed, consisting of:

℞	Liq. plumbi subacetatis	16.00 gm.
	Liq. carbonis detergentis	80.00 gm.
M.	Sig.: Two teaspoonfuls in pint of hot water as a lotion and apply as compresses for ten minutes, twice a day.	

There was also prescribed an ointment:

℞ Ichthyoli	1.60 gm.
Hydrarg. oxidi rubri	4.00 gm.
Camphorae	4.00 gm.
Plumbi carbonatis	8.00 gm.
Lanolin,	
Petrolatum	āā 32.00 gm.

M. Sig.: Rub well into the lesions twice a day, after soaking the hands in the lotion.

Some time after this, the liquor carbonis detergens was painted on in full strength once a day, and the above dilute lotion of liquor carbonate detergens and lead water was used only once a day, in the evening. The ointment was changed to one of:

℞ Emplastri plumbi,	
Petrolatum	āā 30.00 gm.

Melt together over a slow fire, stirring constantly and add:

Liq. cresol. com.	1.20 gm.

M. Sig.: Use on fingers twice a day.

Six weeks after beginning treatment his lesions had all disappeared. In a number of instances in which other applications have failed, resorcin, in less than 4 per cent. strength, has been found excellent.

℞ Resorcini	2.00 gm.
Glycerini	2.00 gm.
Zinci oxidi	7.50 gm.
Cerae albae	1.50 gm.
Adipis benzoatae	50.00 gm.

Dissolve the resorcin in heated glycerin. Melt together the wax and the lard, and add, while constantly stirring, the dissolved resorcin and the well-triturated oxid of zinc. Sig.: Rub in well, twice a day.

The official unguentum acidi borici often acts well; the white precipitate in 2 to 4 per cent. strength in an ointment, may, in some instances, be better than the salicylate of mercury as given in one of the above prescriptions. Some of the best results in treating eczema of the soles, and especially of the palms, have been obtained by Montgomery and Culver by the use of Roentgen rays, after all other lines of treatment have failed, for months or even years.

84 Management of Septic Conditions in Abdominal Cavity. A. M. Willis, Richmond.

80. **Ectopic Gestation.**—Of the forty-four cases analyzed by Taylor, 76 per cent. gave a history of inflammation of the appendages, or it was discovered at the time of the operation. In 81 per cent. of the cases there was a history of irregularity in the menstrual bleeding. In 8.7 per cent. there was a history of amenorrhea lasting to the time of operation. In 69.6 per cent. of the cases of ruptured ectopic sac, the classical symptoms of acute localized sharp pain, with nausea, vomiting, and fainting were present. Of the unruptured cases 92.3 per cent. of the patients suffered from pain on the side of the diseased tube. The breasts were enlarged and tender in 44 per cent. of the cases and in 55 per cent. they showed no change. In the unruptured cases in the series, the average number of white blood cells was 8,670 with 73 per cent. polynuclear cells and 25 per cent. lymphocytes. Excluding the infected cases, the average white blood count was 14,430 and 83.7 per cent. polynuclear cells.

There were four deaths or a mortality rate of 8.7 per cent. Two of the deaths were in cases that had advanced beyond the fifth month. One patient died from shock and hemorrhage and the other from septicemia. Excluding the cases that ended fatally and those in which the operation precluded pregnancy, there were fourteen patients whose history in regard to subsequent pregnancies was obtained. Of these fourteen patients, three had subsequent normal pregnancies. One patient had three children, another two children, and the third had a miscarriage. In addition to these cases of normal pregnancy, there were four cases of 8.7 per cent. of subsequent extra-uterine gestation.

95. **Ureteral Calculi.**—The symptoms of ureteral calculus are not diagnostic and are insufficient to definitely determine either its presence or position except in rare instances. While roentgenography is the simplest and probably the most valuable single diagnostic method for the detection of ureteral calculi, even in the most expert hands, a surprisingly large percentage (22.4 per cent.) may be undetected by it. This large percentage of failures demands the employment of supplementary methods, before excluding stone with any degree of positiveness. By means of collargol ureterograms a calculus occasionally will be shown which the simple Roentgen ray failed to reveal.

In Geraghty and Hinman's experience the employment of the wax-tipped catheter is by far the most accurate method for the detection of ureteral calculi, and this method should be in more general use. In six out of thirty-six cases of ureteral calculi (20 per cent.) seen by the authors in the last two years, it has located a stone in which repeated roentgenograms were uniformly negative. Owing to the great frequency of extra-ureteral shadows in the region of the pelvic portion of the ureter, diagnosis of ureteral stone in this position cannot be accepted without confirmatory information. A considerable percentage of stones which enter the ureter pass spontaneously, and the discovery of a small calculus is not always an indication for immediate operative interference. Unless the stone is blocking completely or producing repeated and violent colic, simple manipulative methods should first be employed. For calculi beyond the juxtavesical portion, displacement with the ureteral catheter, injection of oil or the securing of relaxation of the ureteral wall by using the thermocatheter may, in certain cases, result in the expulsion of the stone. When the stone is in the vesical portion of the ureter, cystoscopic procedures should usually be successful. A study of the authors' cases, as well as different series reported in the literature, shows that a considerable proportion (14.3 per cent. G. and H.; 17 per cent. of 204 cases, Jeanbrau) of ureteral calculi are arrested in the intramural portion of the ureter, a portion which can be readily reached by cystoscopic methods.

96. **Spina Bifida; Tibial Transplant.**—An incision about 10 cm. long was made over the crest of the father's tibia and a rectangular piece of bone about 4 x 6 cm. and 2 mm. thick was removed by means of a circular saw, leaving the periosteum attached and extending over each side for about 1 cm. In this manner the medullary cavity of the tibia was not entered. The graft was immediately placed in a pan of warm normal saline solution and kept there for further use. The baby was etherized and a transverse elliptical incision made over the tumor so as to have the incision removed as far as possible from the anus. The sac was readily exposed and the dissection was quickly carried down to the cleft in the spine. This cleft was about 2 x 5 cm. and situated in the lumbosacral region. An opening was made in the fundus of the tumor, allowing about 300 c.c. of clear serum to escape. This exposure showed the various nerve-roots radiating over most of the sac, especially in the dorsomedian aspect. It was Trout's intention to trim around these nerve roots as is usually done, but each time he pinched or cut one of them with the scissors the child would stop breathing and become cyanotic. He then decided to close up the sac some distance from the ends of the nerve roots, which he did with a continuous plain catgut suture, and then shoved this collapsed tumor into the cleft somewhat after the manner of Schmidt, held it in this position, placed the bone graft removed from the father's tibia over it and anchored it by means of chromic catgut No. 0 sutures. These sutures were placed through the periosteum of the graft, the cartilage of the transverse and spinous processes and any other firm structure the curved needle would grasp. In order to prevent too much pressure on this collapsed sac the graft was bent like a bow and held in this position on all sides by sutures. The skin was sewed up with fine black silk, and silver foil, cotton and collodion dressing was applied. The result was entirely satisfactory.

99. Abstracted in The Journal, Jan. 17, 1915, p. 232.

100. **Periosteal Regeneration of Bone.**—Smith claims that periosteum stripped quickly and with a sharp periosteotome will produce bone in a greater percentage of cases if young animals are used than if fully developed adult animals are employed. Likewise a greater percentage of positive results will be obtained with periosteum which is stripped slowly and with an elevating action of the periosteotome than when the periosteum is quickly torn loose from the compact bone. A very large percentage of positive results can be obtained by using very young animals and small strips of periosteum. Fibrin is a very active stimulant to osteoblastic activity. These conclusions are drawn from considerable experimentation carried on at several different institutions, some under very adverse conditions and others under favorable circumstances. The experiments are not enumerated.

101. **Perforation at Juncture of Cystic and Common Ducts.**—The point emphasized by Lapenta is that a correct *diag-*

nosis was made from the peculiar coma the patient exhibited. The patient was found unconscious, temperature 94⅘, pulse 120, and respiration 40. Breathing was entirely thoracic. Very slight palpation in the region of the epigastrium quickly aroused the patient, causing unbearable pain. It was very clear that a perforation of the duodenum, stomach, or gall-ducts had occurred. No history of previous illness or attacks could be obtained from the patient. Questions were answered incoherently and unwillingly. Considering that there was no blood in vomiting but only a greenish acid liquid, and on the statement of a relative that the patient had never had any gastric disorders, and taking into consideration the comatose state of the patient, which Lapenta always regards in upper abdominal calamities as characteristic of common-duct trauma, he was led to diagnose the case as one of common-duct perforation. A perforation about 7 or 8 mm. in length was found below the juncture of the common duct, and a calculus was protruding from the rent. A cholecystostomy was performed to secure drainage and as an expectant measure for the probable development of a common-duct stricture, in order to afford immediate protection to the dying patient against a biliary obstruction. The recovery was uneventful, the patient being dismissed from the hospital completely cured after three weeks.

106. **Access to Deeper Orbit.**—The essential point in the method practiced by Van Hook is the free removal of the superciliary projection until the orbit is widely open. The author believes that by its use the extraction of the supraorbital nerve will be much facilitated and the results improved.

119. **Button Suture in Anterior Colporrhaphy.**—The operation devised by Wilcox is performed as follows: With the patient on the back and the perineum retracted, the cervix is caught with volsellum forceps and the anterior vaginal wall put on the stretch. A small opening is made through the vaginal mucous membrane just anterior to the cervix. Through this the blades of a pair of blunt-pointed scissors are introduced and worked up between the vaginal and cystic layers by alternately spreading and closing the blades until the two membranes are separated as far as the base of the urethra. Then the vaginal mucous membrane is split vertically and the lateral dissection may be carried as far as desired with the fingers or instruments. While the flaps are drawn taut, a curved needle armed with a double suture of ten-day chromicized gut on which an ordinary pearl shirt button is strung, is passed through from the base of one flap to the other. Three or more similar sutures are placed in the same manner. Then the second set of buttons are threaded on to the sutures and the flaps approximated. Only sufficient tension is made to hold the flaps in approximation without undue pressure. After the sutures are tied over the buttons, and cut off, the flaps are trimmed down until there is about a quarter of an inch of tissue projecting beyond the edges of the buttons. The edges of the flaps are then whipped together with a continuous suture of plain catgut. None of the sutures require removal and the buttons will come away in about two weeks.

120. **Oil-Impregnated Drainage Tubing.**—Attention is called by McArthur to the use of a properly prepared "oil-impregnated" rubber tube in postoperative drainage in localities in which a serofibrinous or hemorrhagic exudate is ordinarily expected during the first twenty-four to seventy-two hours. Suitable pieces of pure para gum tubing are boiled for a few minutes in weak soda solution, to remove traces of the surface sulphur, washed in clean water, dried, and then dry-sterilized in a steam autoclave. The tubing should be one-half the caliber and two-thirds the length of the desired end-results, because of the changed size subsequently induced by the oil. These tubes are then allowed to stand completely immersed in suitable jars of sterile "petrolatum liquidum," U. S. P., for not longer than one week at room temperature. At the end of this time they are removed from the oil with proper aseptic precautions, the excess of oil shaken off, and are preserved ready for use in normal salt solution containing 1:1,000 bichlorid.

132. **Bacillary Dysentery.**—Bryson calls attention to the fact that bacillary dysentery exists to a considerable extent in Texas, a locality not frequently mentioned in literature. Because of the fact that simple or catharrhal dysentery is so common and resembles bacillary dysentery so much during the first few days, Bryson always gives the following old prescription until at least twelve doses have been taken:

Tincture Opii (Deod.),
Ac. Sulph. Arom .... āā f℥i
Magnus Sulph .... ℥i
Syr. Zingib .... q. s. ad ℥vi
M. Sig.: Take tablespoonful in water every three hours. For adults, *children and infants, in proportion to age.*

When convinced that he is dealing with a case of bacillary dysentery, he stops the opiate and pushes the salines vigorously for the next few days, until the amount of mucus in the stool has been greatly reduced. Bismuth may be given in large doses after the active infection is over, as it may coat and heal the irritated bowel. After the bowel has been thoroughly cleansed with salines, and the diet regulated, elevate the patient's hips on the side of the bed, with an oil sheet or pad under him to drain the return flow into a vessel, and pass a sterilized soft rubber colon tube of medium size into the bowel very slowly, avoiding any force. If the tube meets with resistance, stop; and if the relaxation does not permit the tube to pass on, connect it with the syringe and let a small amount of the warm saline solution flow in, it will thus pass without any pain to the patient or injury to the inflamed bowel When passed well into the bowel, let the solution flow with gentle pressure, and when the patient complains of fulness and discomfort, he should be instructed to strain and expel the excess of the fluid, all the while it is flowing in from the syringe. Repeat this as often as indicated during the active inflammation. It is beneficial to use them every three or four days, gradually decreasing as the active inflammation subsides. Warm saturated solution of boric acid is just as safe, and in addition is a mild antiseptic and astringent. A solution of bichlorid of mercury, 1:4,000 or 1:5,000 may be used. The most effective application Bryson has used is a solution of silver nitrate, beginning with about 20 grains to the quart of sterile warm water, and increasing the strength to 40 grains to the quart.

139. **Report of Cases.**—The cases reported by Shelmire are the following: Orthoform dermatitis, multiple nonpigmented sarcoma, multiple neuritis from arsenic paste, xeroderma pigmentosum, leprosy and dermatitis venenata.

9. **Malignant Edema.**—Bell urges making immediate and deep incisions down to the bone, under chloroform, by means of a 6-inch blade amputation knife. These incisions are from 4 to 6 inches in length. They are afterward kept wide open with fenestrated rubber tubes, 1 inch in diameter, passed on transversely through the muscle to a counter incision. Not less than three, and in one case six large openings were made. The wounds were irrigated with solutions of hydrogen peroxid of the ordinary strength, followed by a mixture of the same solution, with an equal quantity of phenol 1 in 100. The wounds were also lightly packed with gauze. Dressings and irrigation were repeated every three hours. A high cradle was placed over the wounded part so as to admit plenty of air. After a few hours (as soon as checking of bleeding would permit) the gauze drainage was removed and only a thin layer of gauze left to cover the wound. It is quite possible that had these wounds been exposed for hours to direct sunlight the author would have had a more rapid result. The wounds have a great tendency to close in a few hours, and this, unless prevented by the surgeon, will bring about the anaerobic conditions which he is trying to avoid. A pair of forceps and the moving about of the rubber tubes will prevent this accident. Night and day special nurses were employed, and since the adoption of this system of treatment (in the last seven cases) there have been no deaths. Recovery took five to seven days.

17. **Pancreatic Infantilism.**—In February, 1902, and March, 1904, Bramwell published the data of a case of infantilism associated with chronic diarrhea, in which the condition was due to defective or arrested pancreatic secretion, and in which the diarrhea was cured and the infantilism removed by the administration of pancreatic extract and by that means alone. Bramwell claimed then that the condition, pancreatic infantilism as he termed it, is a distinct clinical entity, a disease which had not hitherto been recognized and described. The characters of pancreatic infantilism are: arrested bodily and arrested sexual development; intelligence good, no mental defect; no deformity or structural defect of the bones; no visceral disease or derangement except chronic diarrhea, flatulent distention of the abdomen, and defective or arrested pancreatic secretion. The defective or arrested pancreatic secretion Bramwell believes to be due probably to chronic pancreatitis. In some cases the condition (chronic diarrhea and infantilism) is completely cured by the administration of pancreatic extract and by that treatment alone.

The author details the after-history of his case and refers to other cases which have been recorded since he directed attention to the condition. For the past ten years his patient has enjoyed excellent health (with the exception of an attack of dyspepsia, due to errors in diet, during March and April, 1914), and has been regularly at work as a tailor. During the past nine years his bowels have been very regular; he has, as a rule, one motion a day, seldom two; the motions are always formed and natural. Before the pancreatic treatment was commenced there were, on an average, 5 or 6 loose motions daily. Before the treatment the patient had not grown at all for eight years. After the treatment he gradually commenced to grow. He now measures 5 feet 3 inches and weighs 7 stone 13 pounds (101 pounds), an increase of 10⅞ inches in height and 3 stone 5½ pounds (47½ pounds) in weight. The sexual development, which when the patient came under observation was quite infantile, gradually become complete. The patient lost his child-like appearance; his voice, which was high pitched and childish, became low toned and rough.

34. **Spinal Anesthesia in Suprapubic Prostatectomy.**—In the cases reported by Page no failure to obtain muscular relaxation or analgesia occurred. Anesthesia, though slow to appear in three cases, was perfect eventually in 41 cases out of the 43; in the 2 others there were muscular relaxation and analgesia of the bladder. Thirty-four of the cases were operated on without any general anesthesia. Nitrous

oxid and oxygen were given to 4 patients for prevention of mental shock, the spinal anesthesia being perfectly good. In 3 patients a little general anesthesia was given during the skin incision, after which it was withdrawn and no more given. These 3 patients were completely conscious when the skin was being stitched up at the end of the operation. The skin was then completely insensitive; therefore they were cases in which the anesthesia came on more slowly than usual. In two other patients a little general anesthetic was given during the skin incision and stitching up only, none being given during the opening of the bladder or enucleation, muscular relaxation and bladder analgesia being present. Two patients died. One at the time of operation was suffering from uremia. He recovered normally from his spinal paralysis and was no worse at the end of the operation than before and remained no worse for two days, when vomiting and diarrhea came on. The second recovered normally from the spinal injection and operation. Did perfectly well for ten days, when an attack of acute lobar pneumonia came on and he died in a few days.

35. **Tuberculin Administration and Graduated Labor.**—Patients admitted to the Royal National Hospital, Ventnor, undergo the ordinary open-air sanatorium treatment with rest or systematically graded exercise according to the state of the case. A part of the accommodation of the hospital (about a fourth) is, however, set apart for prolonged treatment of selected cases by a course of graduated labor. After selection these patients are on probation for a period of not less than four weeks, and if that term is passed satisfactorily they are taken in as "workers" to the special working blocks, in which they remain until they leave the hospital. Tuberculin has been carefully administered in some of the most promising of these selected "workers" by the intensive method, either "B. E." or "T. R." Slight reactions were occasionally observed. In the rare cases of prolonged reaction the use of tuberculin was discontinued.

As the result of inquiries sent by Taunton to all of the 300 patients whose cases are under consideration, 189 returns were sent in—61.6 per cent. of the cases treated with tuberculin ("T." cases), and 63.2 per cent. of those treated without it ("N. T." cases). The deaths recorded were not markedly different in the "T." and in the "N. T." groups, namely, 8.3 per cent. for both in women and 12.8 per cent. "N. T." men and 16 per cent. "T." men. Among the "N. T." cases 79.1 per cent. of women and 71.1 per cent. of the men were reported as able to do their work, while of the "T." cases only 50 per cent. of the women and 56 per cent. of the men could do so. To put it another way, adding together the men and women, while of the "N. T." cases 26.9 per cent. were unfit for work or were dead, of the "T." cases 46.9 per cent. were so conditioned.

It was apparent that the administration of tuberculin to selected phthisic workers does not shorten, but, on the contrary, it lengthens, the duration of treatment. The use of tuberculin does not increase the ability to do work. It appears not only to delay the improvement in working ability, but it also diminishes the ultimate ability achieved by a more prolonged course of treatment. So far as gain in weight and the rate of gain enable one to judge, the administration of tuberculin is detrimental to the nutrition of patients to whom it is given under these conditions. The after results in fitting patients to do their work after leaving the hospital in these cases are less favorable in cases in which the tuberculin has been used than in the cases in which it has not.

37. **Chemistry of Rice Polishings.**—Polishings were extracted by Fraser and Stanton twice with six times their volume of 0.3 per cent. hydrochloric acid. The polishings after extraction were tested and found valueless. Alcohol was added to the extract so as to bring the mixture up to the strength of proof spirit. The precipitate, which consisted of phytin, was rejected. The filtrate was nearly neutralized, concentrated at a low temperature, and its volume so adjusted that 30 c.c. contained the material soluble in proof spirit from 5 gm. of polishings. Eighteen fowls were fed on polished rice and received once daily 30 c.c. of this solution. Their health was unimpaired. Another lot of polishings was extracted in the same way and alcohol added to the extract as before. To the proof-spirit filtrate sodium hydrate was added so as to make a solution containing 0.3 per cent. of that substance. The precipitate was collected, and the amount of it obtained from 5 gm. of polishings was given once daily to each of six fowls fed on polished rice. The filtrate was neutralized and evaporated at a low temperature until free from alcohol. The volume of the solution was then adjusted, so that 30 c.c. represented the nonalkali precipitable material from 5 gm. of polishings. Each of six fowls on polished rice received 30 c.c. of this solution once daily.

The fowls in neither of these two groups did well and most of them lost weight rapidly. On further examination it was found that 0.3 per cent. of sodium hydrate did not effect complete precipitation. From this it was inferred that the active substance was either separated into two parts or that it has been decomposed by the alkali. It was found that by making the proof spirit alkaline to the extent of 0.5 per cent. sodium hydrate, precipitation was complete. An experiment was then carried out in which fowls on polished rice received daily the alkaline precipitate obtained in this way from 5 gm. of polishings. It soon become apparent that the fowls were not doing well and the occurrence of polyneuritis ended the experiment. In view of the preceding results it was unnecessary to carry out an experiment with the alkaline filtrate. The inference from these experiments was that sodium hydrate in weak solution destroyed the active substance. The authors conclude that they have failed to isolate the curative substance which occurs in rice polishings. It is apparently decomposed during the fractionation and all trace of it is lost. The existence of "vitamin" in the sense that Funk employed that word is therefore disproved.

41 *Premature Separation of the Placenta, and Eclampsia. E. Zarate (Buenos Aires).
42 War Babies. (L'avortement est-il autorisé dans certaines circonstances en dehors des indications d'ordre médical?) H. Hartmann.

41. **Eclampsia with Premature Separation of the Placenta.**—Zarate gives a colored plate showing the "apoplexy" of the uterus and placenta in one of the two recent cases he reports. The eclampsia was very severe in one case but there were only mild and brief convulsions in the other. Both cases terminated fatally for mother and child. In both there was fulminating hemorrhage, absolutely uncontrollable. An emergency hysterectomy was done in one case but the woman died on the table. In the two cases reported here, the premature separation occurred during or just after one of the convulsions. Essen Möller encountered this association of eclampsia and premature separation of the placenta in two of his twenty-nine cases of eclampsia, and Zarate found records of two in twenty-five cases at the clinic for women at Buenos Aires.

34. **Spinal Anesthesia in Suprapubic Prostatectomy.**—In the cases reported by Page no failure to obtain muscular relaxation or analgesia occurred. Anesthesia, though slow to appear in three cases, was perfect eventually in 41 cases out of the 43; in the 2 others there were muscular relaxation and analgesia of the bladder. Thirty-four of the cases were operated on without any general anesthesia. Nitrous

oxid and oxygen were given to 4 patients for prevention of mental shock, the spinal anesthesia being perfectly good. In 3 patients a little general anesthesia was given during the skin incision, after which it was withdrawn and no more given. These 3 patients were completely conscious when the skin was being stitched up at the end of the operation. The skin was then completely insensitive; therefore they were cases in which the anesthesia came on more slowly than usual. In two other patients a little general anesthetic was given during the skin incision and stitching up only, none being given during the opening of the bladder or enucleation, muscular relaxation and bladder analgesia being present. Two patients died. One at the time of operation was suffering from uremia. He recovered normally from his spinal paralysis and was no worse at the end of the operation than before and remained no worse for two days, when vomiting and diarrhea came on. The second recovered normally from the spinal injection and operation. Did perfectly well for ten days, when an attack of acute lobar pneumonia came on and he died in a few days.

35. **Tuberculin Administration and Graduated Labor.**—Patients admitted to the Royal National Hospital, Ventnor, undergo the ordinary open-air sanatorium treatment with rest or systematically graded exercise according to the state of the case. A part of the accommodation of the hospital (about a fourth) is, however, set apart for prolonged treatment of selected cases by a course of graduated labor. After selection these patients are on probation for a period of not less than four weeks, and if that term is passed satisfactorily they are taken in as "workers" to the special working blocks, in which they remain until they leave the hospital. Tuberculin has been carefully administered in some of the most promising of these selected "workers" by the intensive method, either "B. E." or "T. R." Slight reactions were occasionally observed. In the rare cases of prolonged reaction the use of tuberculin was discontinued.

As the result of inquiries sent by Taunton to all of the 300 patients whose cases are under consideration, 189 returns were sent in—61.6 per cent. of the cases treated with tuberculin ("T." cases), and 63.2 per cent. of those treated without it ("N. T." cases). The deaths recorded were not markedly different in the "T." and in the "N. T." groups, namely, 8.3 per cent. for both in women and 12.8 per cent. "N. T." men and 16 per cent. "T." men. Among the "N. T." cases 79.1 per cent. of women and 71.1 per cent. of the men were reported as able to do their work, while of the "T." cases only 50 per cent. of the women and 56 per cent. of the men could do so. To put it another way, adding together the men and women, while of the "N. T." cases 26.9 per cent. were unfit for work or were dead, of the "T." cases 46.9 per cent. were so conditioned.

It was apparent that the administration of tuberculin to selected phthisic workers does not shorten, but, on the contrary, it lengthens, the duration of treatment. The use of tuberculin does not increase the ability to do work. It appears not only to delay the improvement in working ability, but it also diminishes the ultimate ability achieved by a more prolonged course of treatment. So far as gain in weight and the rate of gain enable one to judge, the administration of tuberculin is detrimental to the nutrition of patients to whom it is given under these conditions. The after results in fitting patients to do their work after leaving the hospital in these cases are less favorable in cases in which the tuberculin has been used than in the cases in which it has not.

37. **Chemistry of Rice Polishings.**—Polishings were extracted by Fraser and Stanton twice with six times their volume of 0.3 per cent. hydrochloric acid. The polishings after extraction were tested and found valueless. Alcohol was added to the extract so as to bring the mixture up to the strength of proof spirit. The precipitate, which consisted of phytin, was rejected. The filtrate was nearly neutralized, concentrated at a low temperature, and its volume so adjusted that 30 c.c. contained the material soluble in proof spirit from 5 gm. of polishings. Eighteen fowls were fed on polished rice and received once daily 30 c.c. of this solution. Their health was unimpaired. Another lot of polishings was extracted in the same way and alcohol added to the extract as before. To the proof-spirit filtrate sodium hydrate was added so as to make a solution containing 0.3 per cent. of that substance. The precipitate was collected, and the amount of it obtained from 5 gm. of polishings was given once daily to each of six fowls fed on polished rice. The filtrate was neutralized and evaporated at a low temperature until free from alcohol. The volume of the solution was then adjusted, so that 30 c.c. represented the nonalkali precipitable material from 5 gm. of polishings. Each of six fowls on polished rice received 30 c.c. of this solution once daily.

The fowls in neither of these two groups did well and most of them lost weight rapidly. On further examination it was found that 0.3 per cent. of sodium hydrate did not effect complete precipitation. From this it was inferred that the active substance was either separated into two parts or that it has been decomposed by the alkali. It was found that by making the proof spirit alkaline to the extent of 0.5 per cent. sodium hydrate, precipitation was complete. An experiment was then carried out in which fowls on polished rice received daily the alkaline precipitate obtained in this way from 5 gm. of polishings. It soon become apparent that the fowls were not doing well and the occurrence of polyneuritis ended the experiment. In view of the preceding results it was unnecessary to carry out an experiment with the alkaline filtrate. The inference from these experiments was that sodium hydrate in weak solution destroyed the active substance. The authors conclude that they have failed to isolate the curative substance which occurs in rice polishings. It is apparently decomposed during the fractionation and all trace of it is lost. The existence of "vitamin" in the sense that Funk employed that word is therefore disproved.

Annales de Gynécologie et d'Obstétrique, Paris

August, 1914, to April, 1915, XLI, No. 8, pp. 433-480

41 *Premature Separation of the Placenta, and Eclampsia. E. Zarate (Buenos Aires).
42 War Babies. (L'avortement est-il autorisé dans certaines circonstances en dehors des indications d'ordre médical?) H. Hartmann.

41. **Eclampsia with Premature Separation of the Placenta.**—Zarate gives a colored plate showing the "apoplexy" of the uterus and placenta in one of the two recent cases he reports. The eclampsia was very severe in one case but there were only mild and brief convulsions in the other. Both cases terminated fatally for mother and child. In both there was fulminating hemorrhage, absolutely uncontrollable. An emergency hysterectomy was done in one case but the woman died on the table. In the two cases reported here, the premature separation occurred during or just after one of the convulsions. Essen Möller encountered this association of eclampsia and premature separation of the placenta in two of his twenty-nine cases of eclampsia, and Zarate found records of two in twenty-five cases at the clinic for women at Buenos Aires.

44 *Spontaneous and Traumatic Ruptures of the Dura Mater During Delivery. (Ruptures de la dure-mère cranienne chez les nouveau-nés.) S. F. M. Moreno.
45 Ovarian Fibromas; Two Cases. Metzger and de Kervily.

43. **Relations Between Malta Fever and Gestation.**—Laffont concludes from his personal experience with two cases and analysis of thirty cases he quotes with much detail from the literature, that the ordinary treatment for Malta or Mediterranean fever should be applied regardless of the pregnancy. The only cases in which the pregnancy was artificially interrupted are not encouraging, and Bossi's theories as to the advantage of emptying the uterus as a routine measure in acute infections do not seem to be confirmed by the facts. His

reason for recommending this is the assumption that recently delivered women are peculiarly resistant to infections in general. Laffont advises against lactation, however, especially when the disease is of recent date. The micrococcus is found frequently and over a long period in the vagina, and pains, inflammation and hemorrhage are not uncommon during the course of the disease. Abortion and premature delivery are frequent; the germ seems to be able to traverse the placenta, and the children born at term are almost always weak and many of them succumb. The disease may develop at any stage of a pregnancy and the stress of childbirth may rouse the hitherto latent disease. In this latter case it is likely to be mistaken for ordinary puerperal fever. The micrococci are apt to swarm in breast milk.

44. **Rupture of the Dura Mater During Delivery.**—Moreno examined postmortem the brain of 40 newly born children at Buenos Aires, and in 10 cases he found that the tentorium had been lacerated, with rupture of the falx in 5. Thus, in fully 25 per cent. of the children dying at or soon after birth, the dura mater had been ruptured. This represents 1 in every 105 deliveries at the maternity. He reproduced the rupture experimentally in other infant cadavers by pressure on the sides of the head and describes the mechanism involved. Pressure on the sides of the head is liable with abnormally small pelves, especially if delivery is protracted. In two cases in which the hemorrhage from the rupture was apparently the sole cause of death, the pelvis diameter was 9 and 9.3 cm. Instrumental delivery is most dangerous with the after-coming head.

49 *Rice Flour for Bread Making. (Utilisation de la farine de riz dans la fabrication du pain.) Maurel.

46. **Compression of Lateral Sinus.**—Lannois and Patel report five cases which apparently demonstrate that it is possible to arrest the circulation in the lateral sinus without harm, after ligation of the arteries, in operations on the upper part of the neck and base of the skull. The jugular vein flattens out at once. The sinus becomes permanently obliterated by clots if the compression is kept up for several days. The measure thus wards off both primary and secondary hemorrhage after wounds in this region, and permits operations for arteriovenous aneurysms and removal of foreign bodies.

54 *Subcutaneous Injections of Oxygen; Dosage and Technic. R. Bayeux.

54. **Oxygenation of the Body by the Subcutaneous Route.**—Bayeux extols the advantages of subcutaneous injection of oxygen in treatment of gas gangrene, of chronic suppuration and in infected wounds of the chest and bones, citing various authors who have reported experiences in each of these lines. He has been successful himself in treating hemarthrosis and hydrarthrosis by turning a jet of oxygen into the joint until considerable pressure is exerted within. By this means he has cured in wounded soldiers, in a few days, effusions in the knees that had resisted all other treatment for months. An illustrated description is given of the apparatus he has been using for five years for subcutaneous injections of oxygen, permitting measurement and exact control of the inflow. The thighs and the buttocks are the best points for the injections, and if the inflow is kept below 30 c.c. to the minute the injection is not painful as a rule, although some patients feel discomfort if more than 10 or 20 c.c. per minute is allowed. About 250 c.c. is the average dose, but in acute asphyxia a liter or more might be injected in the emergency. In some cases of asphyxia from a poisonous gas, several liters have been thus injected at once. On the other hand, favorable results have been attained with only 100, 150 or 200 c.c. in persons particularly susceptible to the action of the oxygen. The gas is absorbed most rapidly in asphyxia, and two injections a day might be given. In chronic poisoning, anemia and infections, an interval of two or three days is advisable. In some cases the injections have been kept up for several months, with apparently constant benefit. He punctures the joint and plays the oxygen jet in it until the effusion is eliminated, then injects enough of the oxygen to inflate the synovial membrane. He injects at the rate of 70 c.c. to the minute until the intra-articular pressure reaches 70 cm. (water). He has experimented with intravenous injections of oxygen, but this is still in the tentative stage and he does not advise it.

66 *Standards for Estimation of Condition of Nourishment, etc. (281 erwachsene Menschen mit "centralnormalem" Ernährungszustand.) G. Oeder. Commenced in No. 17.

59. **Bockhart's Impetigo.**—Unna refers to Bockhart's experiments in 1887 on his own body in which he proved that the pus cocci were able to induce suppurative pustular lesions on the skin different from furuncles, although they are liable to run into furunculosis, and possibly lead to sepsis. It is very rare under ordinary conditions of hygiene, but is frequently encountered now among the soldiers, and is liable to develop into a chronic course. Prophylaxis is the main thing, he preaches. "No true pus coccus affection of the skin, no isolated furuncle, no felon should be taken lightly. When any of these have lasted any time true pus cocci are already installed in the neighboring, apparently sound hair follicles, ready to start new impetigo or furuncles. They must be walled off from the rest of the skin with a rampart of coccus-destroying substances." For this he uses ichthyol, or ichthyol or mercury-phenol plaster, or a zinc-sulphur-chalk-turpentine paste, something like the formula given in these columns recently, May 1, p. 1533.

Before applying any of the above he dabs lightly with concentrated phenol the suppurating points and the roots of the hairs around this spot. In case of extensive pyodermia all the pustules must be opened and the entire body rubbed long and thoroughly with soap. Any soap will do, especially soft soap, except tar soap, which, he says, breeds folliculitis. In sharp contrast to eczema, the skin all around the impetigo is sound. All the pustules then, with their environment, are spread with the zinc paste. If an impetigo pustule is deep and tender, it should be treated as described in these columns, April 17, p. 1365, Abstract 47. The parts treated with the paste must be covered with gauze to prevent friction from the clothing, as friction and maceration promote the spread of the impetigo.

61. **Constitutional Purpura.**—Frank remarks that the hereditary character of hemophilia is the main feature which distinguishes it from purpura, as the latter is strictly individual. The symptoms of each are so much alike that purpura might well be called pseudohemophilia, although the petechiae scarcely ever occur to such an extent in true hemophilia, and the joints are spared in purpura. Of the chronic form of purpura, accompanying the individual through life after it is once acquired, Frank cites thirty-four cases from the literature and describes four from his own experience, referring also to a few cases recently published, including Duke's in THE JOURNAL, Oct. 1, 1910, p. 1189. He has never known of complete recovery in any case, and is inclined to believe that in most cases the supposed recovery from an acute attack was merely the subsidence into latency of a chronic purpura which the physician had happened to see during an exacerbation. In the three cases reported in this instalment, the first symptoms developed at the age of 12, and in the first case the hemorrhage proved fatal at the second exacerbation a year later. During the year's interval the child had apparently thrown off the affection. There was almost a total absence of blood platelets—a thrombopeny. In the third case attacks had returned once a year, for six years, lasting for a few weeks each time. In one of these attacks hemorrhages in both eyes compelled enucleation of one and iridectomy in the other eye.

62. **Tests for Acetone.**—Engfeldt modifies Frommer's technic for acetone in the urine by increasing the proportion of alkali. It renders the test so sensitive that it is not adapted for clinical use, as traces of acetone are present in all the body fluids. But for physiologic research the modified test is bound to prove very valuable.

64. **Tangential Wounds of the Skull.**—Sauer declares that if the skull has not been opened by the bullet, it is better to refrain for a time from operating even although the skull has been indented along the course of the bullet. By waiting until the man has reached a hospital where asepsis can be counted on, his chances are much better. The danger from the delay is far less than from the infection which is almost certain when any operation is attempted at the front.

66. **Standards for State of Nourishment.**—Oeder has worked out a formula for the standard weight for men and for women according to the height. Also an index for the condition as regards the nourishment. The latter standard is independent of the height, and both of the age. His previous communication on this *Fettpolsterdickeindex* was summarized in Abstract 120, May 28, 1910, p. 1831. He takes up a fold in the abdominal wall, to the right of the umbilicus, and measures its thickness with calipers. He states here that the normal range is from 2.48 to 2.69 cm., from 1 to 1⅛ inches.

Correspondenz-Blatt für Schweizer Aerzte, Basel

67 *Actinomycotic Suppurative Meningitis; Two Cases. C. Wegelin.
68 *Outcome of Treatment of Lung Diseases in a Swiss Sanatorium. (Dauerresultate des Glarner Sanatoriums für Lungenkranke in Braunwald.) F. Oeri.

67. **Actinomycotic Meningitis.**—The fatal meningitis was traced in one case to a minute latent abscess in the lung, and in the other to a process in the jaw below a carious tooth. The primary lesion may be latent or manifest in such cases, but the meningitis runs an acute course when symptoms develop. The patients were a young man and a woman of 36.

68. **Outcome of Sanatorium Treatment.**—Oeri reviews the present status in 1,365 cases of pulmonary tuberculosis given sanatorium treatment during the fifteen years before 1913. Of the 355 in the first stage, 83.9 per cent. are still living; 54.2 per cent. of the 223 in the second stage and 25 per cent. of the 516 in the third stage. The outcome is not known in 169 cases. Of the first stage survivors, 82.5 per cent. have full earning capacity, as also 80 per cent. of the surviving second stage patients, and 60 per cent. of those in the third stage. He mentions in particular that of the 288 patients who still expectorate, 180 say they use their pocket spit cups regularly and fifty-six use its equivalent. Only twenty-eight have given it up as too much of a bother.

More than 10 per cent. of all the survivors related that they had been handicapped later in their self-support and in their social life by the fact that they had been in a sanatorium. The stigma clings to them, and they complained of the irrational prejudices of their environment. This is particularly to be deplored, as this unreason makes it especially hard for those who are fighting their disease most conscientiously. He thinks physicians have unintentionally bred this tuberculophobia by their efforts to stamp out the disease. It is the task of the profession now to realize, itself, and to teach, that tuberculosis is not one of the diseases which appear in epidemic form, like cholera or typhoid, and which can be avoided by keeping away from them. We must realize that we cannot escape contact with tuberculosis; we encounter it right and left. Instead of thrusting out those afflicted with it, we must train them to help us fight it. This is possible only when physicians combat the fear of bacilli, a fear which we ourselves have planted, and impress on the laity the realization of their natural resisting forces. Not until this is done can we expect that the tuberculous will do their part by applying early for institutional care, and that they will not be deterred by the prejudices of others against the use of prophylactic measures. It is our task to encourage and make it easy for the tuberculous to apply early for instruction and treatment.

69. **Test of Functional Capacity of the Heart.**—It is now ten years since Katzenstein called attention to the importance of the findings when compression is applied to the femoral arteries. He presses with the middle finger the artery at Poupart's ligament, through a single covering with no exposure of the patient, compressing thus the artery on both sides. The blood pressure and pulse are recorded before, and again after the pressure has been applied for from two to two and a half minutes. With a sound heart, the blood pressure is found higher afterward, the pulse slower. If the blood pressure and the pulse beat have not

changed, this shows that the heart is not quite normal, but not actually incompetent; when the insufficiency is of a higher grade, the pulse increases. When the blood pressure is found lower and the pulse is accelerated, this warns of severe functional disturbance on the part of the heart. Its severity is proportional to the extent of the drop in the blood pressure and the increase in the pulse beat. He has applied this test or had it applied once or more times nearly every day of the ten years, and this experience has constantly confirmed the accuracy and the convenience of the simple technic.

The findings with this test show how the heart suffers from chloroform; even a sound heart shows signs of injury up to the twelfth or fourteenth day. With an already damaged heart it may be three weeks before the heart returns to its previous condition. He thinks that these findings warn against letting patients get up early after any operation unless the heart is sound and the operation a minor one. With chloroform and an already weakened heart, the danger of thrombosis is materially greater. Katzenstein advises against any operation when this test shows that the heart is in a bad way unless the indications are vital, and then usually only under local anesthesia. The findings with this functional test warn of the cases in which no operation should be attempted, and of those in which local anesthesia will have to be used. He gives the details of three particularly instructive cases, out of 3,000 in which this test has been applied, to illustrate the important information afforded by it when nothing else suggested that the heart muscle was below par. In one case of pyonephrosis this test warned of the danger from general anesthesia; even under local anesthesia there was a severe collapse and the pulse kept for weeks at 115 or 120, until final recovery followed. There is very little doubt that this patient would not have survived under general anesthesia.

70. **Fixation of Sagging Liver.**—Gross has usually found the ligamentum teres of the liver stout and strong. Pulling on it tips up the liver, and when this heavy organ has sagged it can be restored to place by cutting this round ligament near the umbilicus, drawing it up over the ninth rib and suturing the ends of the ligament together again. This pulled the edge of the liver up 10 cm. higher in the one case in which he has applied this method to date. All disturbances ceased at once and the woman has been in good health since. The edge of the liver can be felt two fingerbreadths above the umbilicus. The ligamentum teres he utilizes also in fixation of the sagging stomach, tying off the pylorus with it, and thus raising the stomach when the ptosis is of the third degree. With the first degree of ptosis of the stomach, the antrum of the pylorus reaches just to the umbilicus. With ptosis of the second degree, the umbilicus lies at about the middle of the antrum. The third degree is represented by the antrum entirely below the umbilicus. When the stomach sags to this extent, he declares that no relief can be anticipated except from an operation.

75. **Venereal Disease in the Army.**—Stern is chief of a special hospital at Düsseldorf for soldiers with venereal diseases, and he rejoices over the fact that the younger men form only a small proportion, 25 per cent., of the soldiers with venereal diseases. He regards this as evidence that the "enlightening" of the public in sexual hygiene is beginning to bear fruit. Wolff at Stettin has reported similar experiences; married men form about 30 per cent. of all the cases, and Stern's experience has confirmed this, that the married soldiers expose themselves most readily to chances of infection. Stern has been impressed further with the large number of extragenital cases of syphilis now being encountered. The increase in the numbers of primary sores on the lip he ascribes in part to the overoptimism of both physicians and laity in regard to the permanent efficacy of salvarsan. People are relying on it too much and thus underestimating the dangers of syphilitic infection.

80. **Agglutination Test After Vaccination Against Typhoid.**—Hirschbruch describes a method of graduated estimation of the agglutinins in the serum which gives instructive findings not only after vaccination, but in all cases suspected of typhoid. The ordinary agglutination test is useless in those vaccinated against typhoid, he says.

82. **Tardy Hemorrhage After Gunshot Wounds.**—Longard refers in particular to wounds in which the artery has been grazed by a bullet, and this damaged part of the wall gives way sooner or later. He has had about thirty-two cases in which sudden profuse hemorrhage came on six or eight days after the man had been shot, but was apparently recovering without ill effects. The wounds often had nearly or quite healed by this time. The artery has to be completely exposed in order to find and ligate the bleeding vessel. There is no chance of a large artery's healing spontaneously after such an injury.

84. **Test for Iodin.**—Schumacher calls attention to a test based on the facts that hydrogen dioxid is able to liberate iodin from its salts and also to oxidate it. Then by adding some substance, such as a 1 per cent. alcoholic solution of benzidin, which changes its tint with oxidation, we can determine the presence of iodin and gauge its amount. The hydrogen dioxid is mixed with an equal amount of the urine to be tested and with one-fifth the amount of the benzidin solution. On heating the upper part of the fluid just to boiling, it turns brown or black if there is iodin present, and a precipitate of the same color is thrown down. Cooling a little and adding chloroform, the latter turns brown or black. Normal urine keeps its tint unmodified or becomes a dark straw yellow. The color change is much more decided with this test than with the nitric-acid technic.

92 *Etiology of Disease of Ovaries and Tubes. (Adnexerkrankungen.) A. Neisser.
93 Trauma and Chronic Infectious Diseases. E. Schepelmann.

92. **Nongonorrheal Pelvic Disease.**—Neisser protests most emphatically against the assumption that inflammatory processes in ovaries or tubes in young women soon after marriage are always of gonorrheal origin. The gynecologists almost invariably affirm this, and when no gonococci can be discovered in either the husband or the wife, they assume merely that the bacteriologic technic was defective. Some of the various germs which are liable to swarm in the urethra that has once been the site of gonorrhea may acquire pathogenic properties enough to set up inflammation in the ovaries or tubes—Neisser thinks there is much to sustain the possibility of this, although it has not been demonstrated to date. This will require the cooperation of both urologists and gynecologists in zealous bacteriologic research, but if it can be proved much harm can be obviated. As things are now, these ovarian and tubal processes in young wives are liable to be given erroneous treatment with antigonococcus vaccines, etc. Besides this, the confident assertion of the gynecologist that gonococci must be responsible for the pelvic mischief, has broken up the happiness of many a young couple and led to divorce proceedings, when in reality no basis for the assertion could be produced.

Progress cannot be made here without the help of the gynecologists; they should examine as extensively as possible the secretions from the uterus and cervix, both with the microscope and with culture mediums, excluding absolutely all admixture of vaginal secretions. The mucus should be taken from the cervix twenty-four or forty-eight hours after careful disinfection of the canal of the cervix.

97 Combination Actinotherapy for Uterine and Mammary Cancer. (Mehrjahrige Erfolge der kombinierten Aktino-Therapie bei Karzinom des Uterus und der Mamma.) G. Klein.

94. **Eclampsia at Fourth Month of Pregnancy.**—The necropsy findings in the case reported explained the sudden death of the woman of 27 as the result of rupture of a sclerotic cerebral artery in consequence of the sudden rise in blood pressure during an eclamptic convulsion. The woman had a chronic kidney affection and was in the fourth month of pregnancy. There had been no convulsions before this severe one which proved fatal, but the liver showed the changes characteristic of eclampsia.

96. **Serodiagnosis of Pregnancy.**—Petri's extensive clinical and experimental research has elicited a number of new facts, he says, which have an important bearing on the parenteral digestion of albumin, especially from the obstetric and gynecologic standpoints. The tables and the details of the experiments show the wide scope of the work undertaken. Among the new facts thus learned are that the same conditions as follow parenteral incorporation of the individual's own serum can be artificially induced in animals by causing the production of a hematoma. Ferments are formed after absorption of the serum albumin in the blood effusion, and these ferments are able to digest various organ tissues, including placenta tissue. For this and other reasons cited, he says that the Abderhalden reaction will always be positive in pregnant women, but it will also be positive in the nonpregnant whenever conditions are present, such as pathologic or mechanical processes causing extravasation of blood, which permit the absorption of the individual's own albumin. The albumin-splitting ferments are probably mobilized at once after intravenous introduction of unputrefied albumin from the individual or from another individual of the same species, man or animal. The duration of the action of the ferments is probably limited to a certain period of time.

98. **Action of Peroxids and Sugar on Anaerobes.**—Spiro writes from the Institute for Physiologic Chemistry at Strassburg to offer an explanation for the undoubted benefit realized in treatment of the wounded by hydrogen dioxid and sugar. The sugar modifies the medium and this in turn acts on the germs in the medium. Those that have been having the upper hand are crowded out, and harmless ones gain the supremacy. The bacterial growth is different when there is sugar present, and the products of the bacterial growth are different. For example, a putrefying solution of yeast smells of indol; if sugar is added, there is no trace of indol to be detected with any tests. Modifying the medium modifies the bacterial growth, and this may mean everything in case of a wound, as wounds swarm with all kinds of bacteria. He ascribes the favorable action of hydrogen dioxid to its physical properties; it cleans out the wound, floats out on its foam debris and bacteria from the depths and crevices, bringing them to the surface where the light and air or local measures can destroy them more easily.

100. **Typhoid Spondylitis.**—A man of 59, toward the close of an ordinary attack of typhoid, suddenly developed attacks of chills and high fever suggesting pyemia. This was finally explained, after a month, by pains in the lumbar region from a typical typhoid spondylitis. The pains were relieved by a plaster corset, but he was never entirely free from pain for eight months and the fever kept up for the same length of time. Recovery followed at last, apparently complete. Agglutination was pronounced at 1:200 even after eight months. The pain with typhoid spondylitis is more intense than with tuberculosis of the spine, and is aggravated by the slightest movement or lightest touch, and is not relieved by drugs, not even morphin in the usual dosage. The tenderness is localized in the apophysis of one or two vertebrae. In 80 per cent. of the cases on record, about 100, the lumbar region was the seat of the trouble. The affection may linger for two years or more.

102. **Rapid Restoration of Function after Suture of Nerve.**—Thiemann reports a case which he thinks is a record breaker in that complete paralysis of the foot and the most intense and continuous pains, which had followed a gunshot wound of the knee, were cured by resection of 3 cm. of the cicatrized nerve and suture of the stumps. The pain was arrested at once, and the man was able to move his toes by the end of the second week and the whole foot when the cast was taken off in the third week. Both the wound and the operation healed by primary intention.

103. **Suture of Peripheral Nerves.**—The technic for separating a nerve embedded in cicatricial tissues and also for partial or complete suture are described, with one illustration. If there is suppuration no attempt should be made until the inflammation has subsided. Fistulas in the vicinity and sequesters are also contraindications. The sound nerve should be touched with instruments as little as possible. The plaster splint should be applied for two weeks with the nerve two-thirds relaxed, then relaxed still more for a week, and then gradually stretched.

Steinthal presents data from times of peace which show that even when all conditions are favorable the outcome of suture of a nerve is not so favorable as generally assumed. In the war wounds the nerve is damaged much more than is the case usually in the injuries outside of war. He has sutured the nerve in twenty-three cases and released it from pressure of scar tissue in thirteen others. He recalls that operation must be delayed until all inflammation is past, and warns that too great hopes must not be placed on it. The wounded must be informed that the operation is unconditionally necessary but that a complete success cannot be guaranteed.

110. **Complement Fixation as Test for Typhoid.**—Felke states that in 39 persons vaccinated against typhoid, the agglutination test gave nearly constant positive findings while the complement-fixation test was constantly negative. In 9 typhoid cases, agglutination was positive and also the complement-fixation test, as also in a few convalescing from typhoid. He thinks that the complement-fixation test may thus prove of assistance in diagnosing or excluding typhoid in persons who have been vaccinated.

111. **Opium-Bromid Treatment of Epilepsy.**—Kellner has followed Flechsig's technic in treatment of 250 epileptics since 1906 and has never witnessed any harm from it. His impression on the whole is favorable and he asks those who denounce this method whether they can show any better results than his own average of 25 per cent. essentially improved and all more or less modified for the better. The opium is given three times daily for fifty days, beginning with 0.05 gm. of the extract of opium at a dose, increasing to a maximum of 0.29 gm. This is the highest dosage, calculated for an otherwise healthy adult. The fifty-first day the opium is stopped and bromids given, in the Erlenmeyer mixture, three times a day. The dosage here must be cautiously individualized and supervised, watching for signs of intolerance or bromism and slowly reducing the dose if such appear. Sudden suspension of the bromids almost inevitably brings back the seizures. His usual dose of the bromid mixture for a strong adult is 5 gm. a day: 1 gm. in the morning and 2 at noon and again at evening. This is increased to 6 gm. in a week and to 7 gm. after another week. He never goes above this latter dose, but thinks the bromids will have to be taken all the rest of the life if the epilepsy has been cured by this course of treatment and prolonged observation has shown that a certain dose can be kept up indefinitely without harm.

He relates a few typical instances of the benefit from this method of treatment. One patient was a young man who had had for years several seizures a week, rebellious to all the measures applied by various physicians. He was the only child of wealthy parents and was intelligent and well brought up. During the last two years he had had periods of wandering, losing his identity. He took the opium-bromid course in 1910 and had his seizures as usual during the fifty opium days. They stopped when the bromid was begun and he has never had any seizures since. As an extra precaution he returns once a year and takes the whole course over again, and keeps up the bromids all the time, taking constantly his 5 gm. a day. He feels and lives like a perfectly healthy man. Some other cases are reported to show the seizure-provoking influence of alcohol; even half a glass of light wine may bring on an attack after months of freedom.

113. **Importance of Plaster Casts in Treatment of Wounds in War.**—Läwen expatiates on the great value of fenestrated plaster casts in treatment of nearly all kinds of wounds. He is referring here in particular to wounds of the skull, and gives several illustrations of the casts he uses for wounds of the front or side of the skull. The cast leaves the wounded part exposed but otherwise embraces the head and thorax. It materially facilitates changing the dressings, as the wound can be dressed without moving the head. The immobilization relieves the pain and quiets the patient while the brain benefits by the absolute repose thus enforced. If the patient has to be taken elsewhere the cast protects him against injury.

131 Pedunculated Skin Flaps to Cover Stump End. (Hautplastik statt Nachamputation.) A. Schanz.

128. **Celluloid Not Durable to Close Gap in Skull.**—Funke demonstrated in 1908 a boy who had worn a large celluloid plate for five years as a covering over an extensive defect in the skull. The perforated plate measured 7 by 12 cm. and healed in place without reaction. The sixth year two fistulas developed in the scalp, and he exposed the plate to investigate. He found it broken at several points, the celluloid crumbling, having lost its elasticity and firm structure. A gold plate was introduced in its place and the soft parts healed over it without reaction.

130. **Technic for Amputations.**—Chlumsky insists that the more of the limb that is saved, the better the functioning later. Also that it is wiser to use some kind of prosthesis from the earliest possible moment as the stump heals and behaves differently when it is being actively used. Much is lost that can never be regained if the limb is not used until after retraction, etc., are complete. Some simple artificial limb should be applied as early as possible, changing later to the final prosthesis to be worn.

133. **Pregnancy Kidney and Eclampsia.**—Stoeckel's communication is a reply to Gessner's article with this title which was summarized in these columns March 6, 1915, p. 865. Stoeckel denounces his premises as mistaken and his advice as fraught with danger.

134. **Conservative Surgery of the Ovaries.**—Löhnberg reports two cases in which there did not seem to be a trace of normal ovarian tissue as both ovaries were changed into cystomas. Yet some of the cystoma tissue was left on both sides at the operation in the hope that menstruation might continue. This hope was realized, and the young woman not only menstruated regularly thereafter, but conception occurred. In the other case there had been amenorrhea for

three months at the time of the ovariectomy. Seven months later there was an apparently normal menses, but it did not return afterward and the state of the internal genitals thereafter corresponded to that of the menopause.

May 2, No. 35, pp. 545-560

137 Strangulation in Hernia of Appendices Epiploicae; Alleged Twelfth Case on Record. R. Mosti.

135. **The Hemorrhoid Syndrome.**—Pascale reports the case of a man of 60 with hemorrhoids for ten or twelve years and a general tendency to sluggish metabolism. A recent accident to one eye was followed by glycosuria, and then came pains suggesting gallstone trouble, and signs of cystitis. The syndrome thus included glycosuria, cholelithiasis and bladder trouble, but Pascale's analysis and the results of treatment demonstrate that the whole syndrome was merely the manifestation of the condition typified by the tendency to hemorrhoids. Measures to correct this tendency and restore the circulation to normal were followed by the subsidence of the other trains of symptoms, as he relates in detail.

136. **Recuperation of Strangulated Intestine.**—Scandola gives an illustrated description of the findings in two series of experiments on dogs. In the first he shut off a loop 30 cm. long from the rest of the circulation by ligating the artery and vein at each end of the loop. The loop was then resected after six, twelve, eighteen or twenty-four hours and examined under the microscope. In the second series the same ligation was done but the ligatures were removed six, twelve or eighteen hours later and the surviving dogs were killed after an interval of three weeks. Eight dogs were used in all and the results were concordant in that the loop of intestine was able to recuperate whenever the injury from the temporary strangulation was restricted to the mucosa, or the other coats of the intestine were but slightly affected. Even quite serious changes in the mucosa retrogressed, but pronounced changes in the outer layers proved inevitably fatal. Nothing was found to differentiate the strangulated portion in the six-hour animal.

139 *Weiss' Potassium Permanganate Reaction in the Urine. (Sul valore clinico della reazione di Weisz.) A. Ferrannini.
140 Case of Syphilitic Meningomyelitis. U. Scinicariello. Commenced in No. 17.

139. **Test for Chromogen in the Urine.**—Ferrannini discusses the experiences that have been published by others, the technic, the chemistry involved, the reaction in the healthy and in acute and chronic nontuberculous affections, and in various forms of tuberculosis. He also compares the findings with this test with those of the diazo and the tuberculin skin test. The chromogen reaction is not specific for any disease, but in an acute disease, other than typhoid, a positive and pronounced reaction obtainable for several days in succession, strongly suggests tuberculosis. In chronic disease, severe and of long standing, an intense and constant reaction testifies also to the tuberculous nature of the disease, and a negative reaction excludes this unless the disease is in its terminal phase. In tuberculosis, if the reaction is intense and constant, the outlook is unfavorable even although the clinical course seems promising. On the other hand, a faint and inconstant reaction offers a favorable prognosis almost regardless of the clinical course at the time. The long bibliography appended is nearly all Italian. About a dozen French articles are listed but no British or American articles.

Tumori, Rome

March-April, IV, No. 5, pp. 509-632

141 *Primary Cancer of Aberrant Mammary Gland Tissue. (Carcinoma primitivo di un lobo aberrante presternale della mammella.) L. Stropeni.
142 *Primary Tumors of the Pericardium. G. Forni.
143 *Chorioepitheliomatous Tumors in Testicles and Ovaries. (Contributo allo studio dello spermioblastoma a tessitura corioepiteliale.) D. B. Roncali.
144 Gastric Leiomyomas. (Contributo alla conoscenza dei tumori a fibre muscolari liscie dello stomaco.) F. Nassetti. To be continued.

141. **Cancer in Aberrant Mammary Gland Tissue.**—Stropeni's patient was a woman of 57 with an adenocarcinoma in front of the sternum. It was removed three months after the first symptoms had been noted. The microscope revealed the structure to be that of an aberrant lobe of the mammary gland, without any connection with the latter. There has been no tendency to recurrence during the year since although the tumor had been of an unusually rapid and malignant growth.

142. **Primary Tumors of the Pericardium.**—Forni has compiled from the literature fifteen cases and reports another from his own experience. The ages of the patients ranged from 15 to 73, and all were malignant growths but two, but nearly all were necropsy surprises. Even when the malignant disease was known, its exact localization was impossible during life as a rule, or else it was impossible to differentiate the nature of the heart trouble known to exist.

143. **Cancer of the Testicle.**—Roncali refers in particular to tumors of chorioepitheliomatous structure. He regards them as essentially analogous to physiologic embryos; they are pathologic embryos. Chorioepitheliomas of the testicle were long supposed to be sarcomas, but improved technic proved this a mistake. Roncali has encountered two cases, as he describes in detail. The first patient was a young man of 18 who had first noticed signs of a tumor in the scrotum two months before its operative removal. The growth involved both the testicle and the epididymis. A large metastatic tumor developed later in the kidney region, and proved fatal eight months after the first operation. The second patient was also a young man; he was extremely debilitated when first seen and symptoms in the lungs led to the diagnosis of fulminating tuberculosis. He died a few days later and nodules of a neoplastic nature were found in the lungs, suggesting the structure of a chorioepithelioma. The testicles were examined when the above was determined, and the right testicle was found to be the seat of a typical chorioepithelioma, the structure the same as in the nodules found in the lungs, liver, kidneys and spleen.

149 *Localization of the Pain with Chronic Disease of the Pancreas. C. G. Vervloet.
150 Trigeminal Disturbances from Tumor in the Brain as Aid in Localization. C. T. Van Valkenburg.

149. **The Pain in Differential Diagnosis of Chronic Disease of the Pancreas.**—Vervloet gives the details of six cases to show that pain is not so rare with chronic pancreatitis as some assert, and that its location is characteristic, as also its persistency, long duration, and sometimes its severity. Even when there is no spontaneous pain it may be elicited by pressure. The pain in the lumbar region is most characteristic, but there may be pain in the stomach region and along the median line and in both flanks; in the left hypochon-

drium; the lumbar vertebrae; the upper third of the sacrum; a region a few centimeters wide along and to the left of the lumbar vertebrae; the left arm and hand; the left thigh to the knee; the left scapula and shoulder, the left side of the neck and the ear. One case of old duodenal ulcer presented nearly the entire array of the above localizations of the pain. In one case an operation was done for supposed gallbladder trouble, but no stones were found, merely torpid chronic pancreatitis, and it was learned then, too late, that the man had had pain in both scapulas. A few weeks after the operation, pressure on the lumbar vertebrae induced pain. The lumbar pain is more instructive than pain in the stomach region, as the latter may occur with various affections. In the sixth case reported the pain was more on the right side; the first and second lumbar vertebrae were tender, and a very painful point on pressure was found under the twelfth rib close to the spine. Necropsy revealed a cancer in the head of the pancreas.

Norsk Magazin for Lægevidenskaben, Christiania

May, LXXVI, No. 5, pp. 557-696

151 *Direct Transfusion of Blood. R. Ingebrigtsen.
152 *Operative Removal of Emboli in the Arm. J. Nicolaysen.
153 *Disease of the Ductless Glands. (Bidrag til de endokrine organers klinik.) L. Dedichen.
154 *Syphilis and Tuberculosis. H. Sundt.

151. **Direct Transfusion of Blood.**—Ingebrigtsen tabulates fifty cases with all the data, as compiled from the literature, in order to acquaint the profession in Norway with the advantages and the technic of Crile's method of direct transfusion of blood. His list includes articles on the subject in The Journal. He classifies the cases according as the transfusion was done for a constitutional hemorrhagic tendency, hemorrhage from the digestive tract, postoperative and septic anemia or puerperal or other uterine hemorrhage or pernicious anemia. In the six cases in this latter group the results were not especially encouraging. The transfusion in thirteen cases rescued the patients from imminent death. He also gives the minute details of a case in his own experience in which a girl of 8 had lost so much blood from uncontrollable epistaxis that the heart was scarcely able to keep beating. During the transfusion the pulse dropped from 120 to 86 and the child promptly recuperated. The only pathologic finding in the blood is the scarcity of blood platelets; the symptoms observed at the time and during the months that followed suggest a tendency to chronic purpura and the prognosis is reserved although the transfusion can be repeated at need in case there is further trouble from the hemorrhagic diathesis. During the year since she has had one attack of slight hematuria and her lips have bled a little at times.

152. **Operative Removal of Embolus in Both Arteries in the Arm.**—In Nicolaysen's case the heart seemed to be sound but pains in the fingers of the right hand, preceded for a few months by occasional numbness, indicated obstruction of the circulation. The pain grew more serious and the second week the diagnosis of embolism was beyond question. The embolus was supposed to be at its usual site, the bifurcation of the brachial artery. It was exposed under local anesthesia but no traces of an embolus could be found here nor in the upper half of the radial or ulnar arteries. If the diagnosis of embolism was correct, there must be two emboli, one in the radial and one in the ulnar artery, and when the fingers began to show signs of gangrene, three days after the other operation, the lower half of the ulnar artery was exposed and was seen to be bulging over a 2 cm. stretch; pulsation was evident above but none below this bulging portion. An incision 1.5 cm. long was made and the embolus protruded at once and was readily extracted whole. The interior of the vessel seemed normal, and pulsation became manifest below at once after the embolus had been extracted. A week later the radial artery was exposed and the embolus was removed in the same way only that it was twice as long as the first and broke while it was being taken out, and the lower part had to be scooped out. The circulation returned at once in the hand; there was no further pain and the radial pulse was good when last inspected, two months later. It is often a difficult matter to locate the embolus exactly, and the artery often has had to be exposed at several points before the right place was found. According to the experiences on record, it seems as if thirteen hours' obstruction of the circulation is the limit for possible recuperation after complete obstruction. But in Nicolaysen's case the vessel walls did not seem to have been damaged by the distention from the emboli although nineteen days had elapsed after the first symptoms before they were both extracted. The emboli were also found quite loose, not adherent at any point to the vessel wall. His patient was a man of 52, previously healthy. Angiosclerosis is accepted as the fundamental cause for the embolism; the heart is apparently normal.

153. **Disease of the Ductless Glands.**—This address describes the leading affections for which one or more of the ductless glands are now regarded as responsible, citing typical instances of each, with eighteen illustrations.

154. **Syphilis and Tuberculosis.**—Sundt quotes Calot to the effect that it would be better if physicians in charge of lung sanatoriums would think oftener of syphilis, and if syphilologists thought oftener of tuberculosis. Sundt is chief of the seashore antituberculosis sanatorium at Fredriksvern, and he says that in a comparatively large number of cases the patients sent to the hospital are not infected with tuberculosis or, if infected, the symptoms which led to their hospitalization were not any for which the tuberculosis was responsible. In 40 cases of hip-joint disease during the last three years, 27.5 per cent. proved to be nontuberculous as also 20.7 per cent. of 29 cases of knee diseases. In nearly all of the nontuberculous hip-joint cases, the trouble proved to be Perthes' juvenile deforming osteochrondritis, but the knee affections were nearly all of syphilitic origin, namely, in 4 out of 6. The Wassermann reaction was positive in these and also in a surprisingly large number of the patients with other affections, even in many with unmistakable tuberculous lesions. The patients were mostly children, and latent syphilis masqueraded as tuberculosis or "scrofula" in a surprisingly large number or accompanied unmistakable tuberculosis. He gives an illustrated description of several cases; in one both knees were affected after a trauma and had long been treated as for tuberculosis while destructive lesions in the palate had been treated for lupus. The tuberculin reaction was positive as also the Wassermann, and treatment on this latter clue soon restored the child to clinical health. He adds that a similar sequence was encountered soon after in another case: trauma; bilateral knee trouble, followed by a destructive affection of the nasopharynx. Other cases are cited to show that syphilis alone is able to induce the classical picture of "scrofula" in its most typical form. All these patients in this group presented merely the late manifestations of inherited syphilis; in none of them had it been recognized, but tedious treatment had been long enforced for tuberculosis or lupus. There are no absolutely reliable differentiating clinical signs; a primary localization of tuberculosis in the nasopharynx is of very rare occurrence. Tuberculous lesions generally spread superficially, the syphilitic burrow deep. The tuberculin test is most instructive when it induces a focal reaction, but this is rather an exception than the rule. When the findings are dubious, a course of treatment as for syphilis may decide the question; we know that the Wassermann may be dubious even with known syphilis. He reiterates that we must remember that not everything that subsides under potassium iodid is syphilis, and that not all that is syphilis subsides under it. Sixteen cases are reported and discussed showing the many problems presented by the coincidence or mistaken diagnoses of syphilis and tuberculosis. Since the beginning of 1915, 5 of the 22 new admissions to the sanatorium responded positively to the Wassermann test. They had been sent in with the diagnosis of tuberculous disease of the hip joint, foot, knee or face and larynx.

STOMACH CARCINOMA

ITS MEDICAL ASPECTS *

JOSEPH COLT BLOODGOOD, M.D.

BALTIMORE

These observations are based on 184 cases of carcinoma of the stomach which have been observed in the Surgical Pathological Laboratory of the Johns Hopkins Hospital during a period of almost twenty-five years. The majority of the patients come from the surgical clinic of Professor Halsted of the Johns Hopkins Hospital. All of the cases recorded in this surgical clinic are here. A number of cases have been received from Dr. Finney's clinic at the Union Protestant Hospital. All of the cases observed in the surgical clinic of St. Agnes Hospital are included in this list, and there are a few from other hospitals.

These 184 cases may not represent the entire experience of the surgeons connected with the Johns Hopkins Hospital, but it is my opinion that they represent it sufficiently to give a clear picture of our experience with cancer of the stomach.

Fig. 1 (Case 1).—External view of the mass removed.

I have gathered from the reading of the literature that those surgical clinics, in which the total number of cancers of the stomach was larger than the total number of ulcers of the stomach, observed a larger percentage of inoperable cancer and a smaller percentage of cures among the cases in which resection of the stomach was possible, than those clinics in which the number of ulcers of the stomach exceeded that of cancer.

This is true for the cases which I have recorded.

In the Surgical Pathological Laboratory up to date our figures are as follows: stomach ulcer, 132 cases; stomach carcinoma, 184 cases. Cancer, therefore, has been more frequently observed than ulcer.

The figures as to the proportion of operable and inoperable cases of cancer are: no operation, 45 cases; exploratory laparotomy, 49 cases; gastro-enterostomy, 41 cases; total inoperable cases, 135; resection, operable cases, 49.

This demonstrates that in only 26 per cent. of the cases has the cancer of the stomach been operable, in 74 per cent. inoperable.

Table 1 illustrates the percentage of operable and inoperable cases during five-year periods from 1890 to 1915.

The first cancer of the stomach was observed in 1890. The first gastro-enterostomy for cancer was performed in November, 1892. The first exploration for inoperable cancer of the stomach was done in 1895, the first resection in 1898.

The table clearly illustrates that the experience of this clinic with cancer of the stomach really did not begin until 1905—ten years ago. From 1890 to 1905, a period of fifteen years, there were but thirty-five cases of cancer of the stomach, of which nine, or 25 per cent., were operable. In the following five-year peoriod, from 1905 to 1910, the total number of cases increased rapidly to seventy-six, of which only twelve, about 16 per cent., were operable. More cases, therefore, of cancer of the stomach were referred to the surgeon for consultation or operation, and we observe that in twenty-one cases the inoperability was so clear than no operation was done.

Fortunately, in the next five years — from 1910 to 1915 — a distinct change has taken place. The total

Totals	3	12	19	76	73	183

---

* Address of the President before the American Gastro Enterological Society, Baltimore, May 10, 1915.

number of cases so far is seventy-three, of which twenty-eight, or 39 per cent., were operable. These figures surely demonstrate that patients with cancer of the stomach are being recognized earlier and referred to surgical treatment at a more favorable period. The no-operation cases have decreased from twenty-one to twelve, the gastro-enterostomies from twenty-one to thirteen cases.

Here we have the first evidence of a favorable turn in events.

I have also observed that during these five years, for the first time the total number of ulcer cases was greater than the total number of cancers. These figures will be brought out more elaborately in a second paper.

Up until 1910, among twenty-one cases of resection, there have been two cures — a little less than 10 per cent. of the operable cases, or two cures among a total of 111 cases, or 1.7 per cent.

Up to the present time, among the twenty-eight cases of resection between the periods of 1910-1915, there is one patient still living in whose case it will be five years since the operation in August, 1915.

If the patients still living in this group remain well, the percentage of cures may be increased from less than 10 to more than 20 per cent.

These figures, although small, seem to confirm my impression gathered from the literature, that when the total number of ulcers of the stomach in a surgical clinic exceeds the total number of cancers, the percentage of operable cases in the latter group increases, and with this there is an increase in the number of five-year cures.

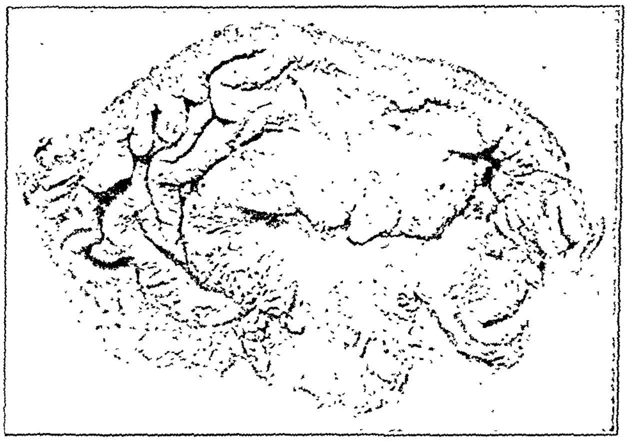

Fig. 2 (Case 1).—Surface view of the longitudinal section.

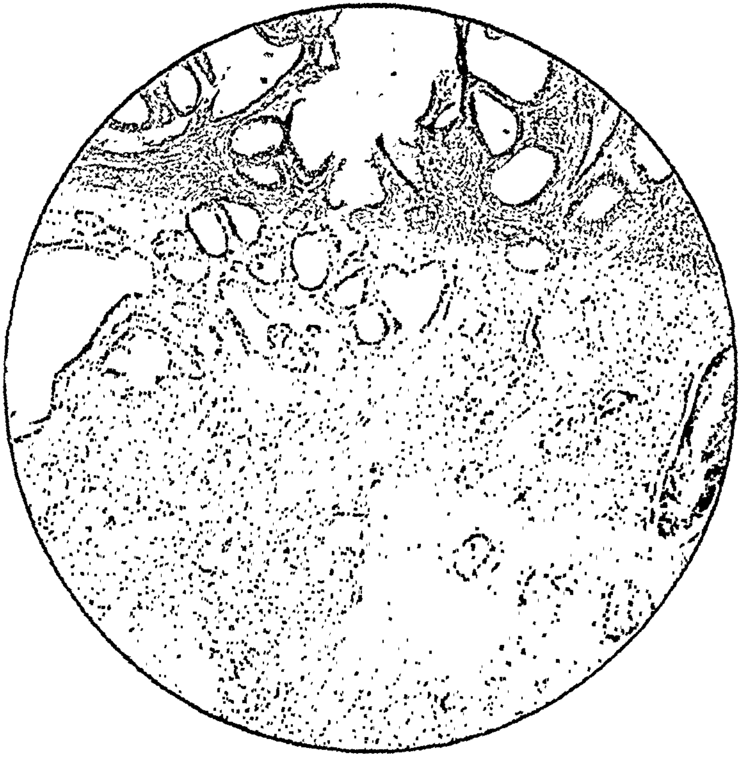

Fig. 3 (Case 1).—Adenocarcinoma.

I do not wish to enter here into the discussion of the relation of ulcer to cancer of the stomach, but the figures of these observations are very suggestive. At least they suggest a definite practical way by which the number of cures of cancer of the stomach may be increased.

Table 2 attempts to illustrate the relation of the duration of the disease to the operability of the cancer. Of course, in computing a table of this kind there is considerable opportunity for error, but if I have made mistakes in this table, it is on the side of shortening rather than lengthening the duration of the disease. I have excluded statements such as "year, or years, of indigestion," or a history of one or more previous attacks that suggested gastric ulcer. I have taken as the duration of the disease the period of continuous symptoms. The chief symptom has been abdominal discomfort in the region of the epigastrium aggravated by eating.

Nausea, belching, vomiting, vomiting of blood, and blood in stools, loss of weight and strength, whether present or absent, has not been considered in estimating the duration of the disease. In all of these cases, discomfort of various degrees has been noted in the history, and this discomfort has always been made worse by eating solid food.

This, therefore, is a very conservative estimation of the period of continuous symptoms.

TABLE 2.—RELATION OF DURATION OF DISEASE TO OPERABILITY OF CANCER

	1 month to 3 months	3 months to 6 months	6 months to 1 year	1 year to 2 years	2 years to 5 years	Over 5 years	Totals
No operation	6	6	5	7	6	4	34
Exploration	5	10	10	10	10	1	46
Gastro-enterostomy	8	7	14	4	5	1	39
[illegible]	19	23	29	21	21	6	119
Resection, operable	8	7	8	6	9	2	40
Totals	27	30	37	27	30	8	159

These cases have been divided into six groups.

The most remarkable finding is that the percentage of operability is about the same in each period.

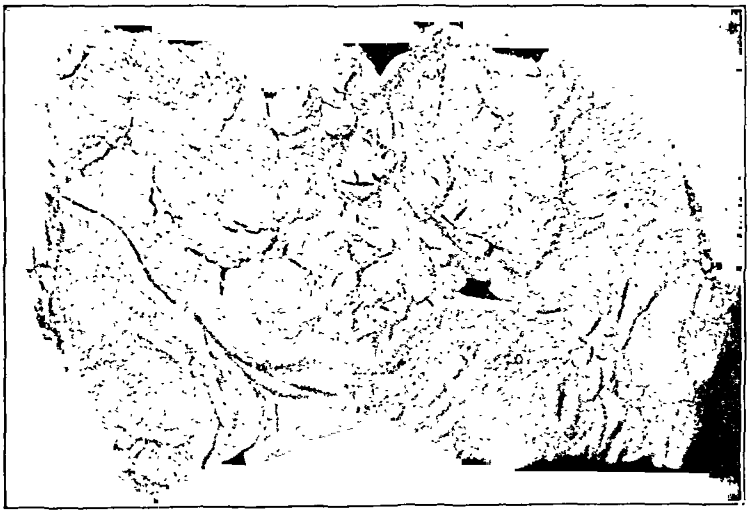

Fig. 4 (Case 2).—Surface view of the removed portion of the stomach.

If cancer of the stomach began as cancer in every instance, it should follow that with the longer period of the disease the percentage of operable cases should decrease; but this is not so.

In fact, among the cases in which the symptoms had been present only three months, the percentage of operable cases is 29. In the next period of three months it falls to 23. In the next period of six months it falls to 21. The figures 29, 23 and 21 per cent. show that with an increase in the duration of the disease, the percentage of operable cases decreases slightly; but in the next two periods, the first of from one to two years, the second from two to five years, the percentage of operable cases increased slightly, so that the figures for the cases in which the duration of the symptoms is less than three months are about the same as for those in which the duration of the disease is from two to five years—29 and 30 per cent., respectively.

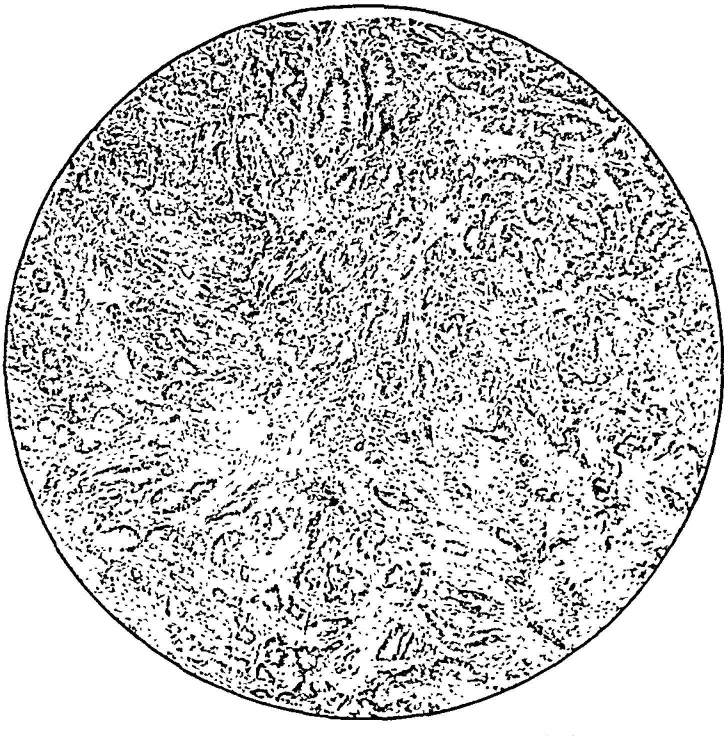

Fig. 6 (Case 2).—Photomicrograph of a section through the ulcer.

In my studies of cancer situated in other localities, such as the breast, lip, tongue, rectum, colon, etc., I have found similar percentages. We have positive evidence that cancer in some individuals grows more rapidly during the same period of time than in other individuals, so that these patients, who have what may be called acute carcinoma, are forced to seek surgical aid early after the beginning of the symptoms because of the rapid growth of the neoplasm. These cases, appearing in the columns of earlier interventions, always increase the percentage of inoperable, and decrease the proportion of permanent cures. Then, again, when we can observe pretty accurately the development of cancer in a previous lesion not malignant, we know that there is no definite time at which cancer may or does develop in the precancerous lesion.

Fig. 5 (Case 2).—Longitudinal section through stomach and ulcer.

I have thoroughly investigated this in cancer of the lip.

Now, *if a large number of cancers of the stomach* develop in a preexisting lesion not cancer, it is quite possible that we may find operable and curable cases even when the symptoms are of relatively long duration. It seems impossible with lesions of the stomach to differentiate, especially in the early months, cancer from ulcer of the stomach, and even lesions of the stomach from abdominal lesions outside of the stomach, for example, cholecystitis and gallstones, and pancreatitis.

Table 2 impresses me as evidence in favor of the conclusion that many cases of cancer of the stomach arise in lesions of the stomach which were not originally malignant, but were most probably cases of ulcer. There is other evidence in favor of this conclusion which I will bring out in a later paper.

Table 3 gives the duration of the disease and number of cases first in single months up to six, of which there are fifty-seven cases, while in the remaining groups from six months to six years and more there are 115 cases.

This table really pictures the medical aspects. All of these patients have had continuous symptoms for from one month to six years or more. It is very difficult to find out why they finally came for surgical help. Perhaps in the largest number of cases the development of almost complete stenosis of the pylorus has forced them to seek help. This as a rule, however, is a relatively late development. In one case stenosis did develop within two months after the onset of the permanent discomfort, but this patient had had indigestion a number of years.

A few of the patients have sought help within a few months after relatively slight symptoms. These patients had all been seen by good internists and had been subjected to a most rigid examination. Most of these cases have been observed in the past five years.

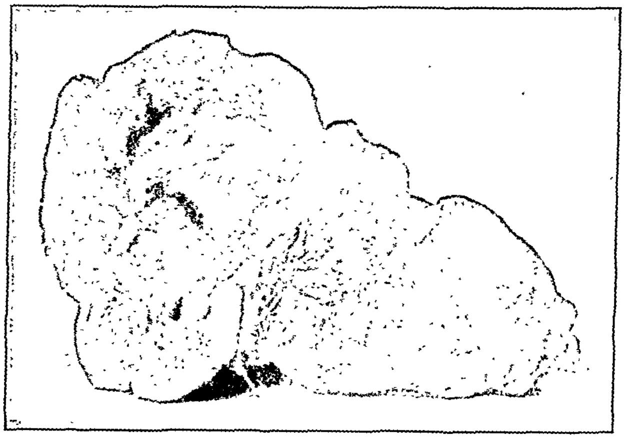

Fig. 7 (Case 3).—External surface of the mass resected.

TABLE 3.—DURATION OF DISEASE BEFORE OPERATION

Five	9	Five	5
Six	13	Six and more	8
Totals	57		115

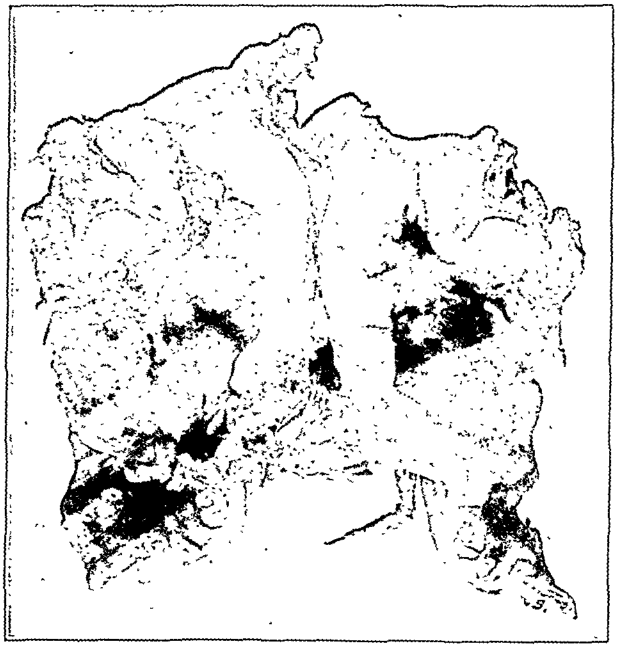

Fig. 8 (Case 3).—Longitudinal section of the mass.

This, it seems to me, is the key to the situation. Our adult population must be informed, with the highest authority behind it, that epigastric discomfort aggravated by eating solid food is a sufficient warning. They must be told that such symptoms by no means mean cancer, or disease that may ultimately end in cancer, but that with these warnings they should seek not treatment, but a thorough examination by a competent physician trained in the investigation of gastric diseases. They must be informed that restricted diet and some medicine will often give them relief; but if the disease is cancer, or something that may ultimately be cancer, such relieving treatment will only increase the danger. A thorough examination is the essential thing, and they must know that a thorough examination consists of repeated gastric analyses and the investigation with the fluoroscope or roentgenograms. No other examination will be sufficient.

Persons so educated with this correct information will undoubtedly have the courage to act. The responsibility, then, falls on the physician. I am confident that, after most careful clinical examination, repeated gastric analyses and Roentgen-ray studies, lesions of the stomach which should be subjected to surgery will not be overlooked, and that our comparative figures will show an increasing number of gastric ulcers, an increasing number of gastric ulcers with microscopic changes suggesting early cancer, an increasing number of operable masses in the stomach which are microscopically distinctly cancer, and an increasing number of permanent cures among the latter. With this earlier intervention, the mortality of gastrectomy will decrease.

When there are nonadherent masses in the stomach, in patients who are in good condition, resection of the lesion in the pyloric half of the stomach should have a mortality of 2 per cent. or less.

There is no doubt that today among trained surgeons the technic of resection of the stomach is far ahead of the opportunities to apply it at the most favorable period.

Inoperability, low percentage of permanent cures after resection, and the mortality of resection are chiefly dependent on delay. There seems no question that every one will be duly and sufficiently warned. If patient, physician and surgeon make no blunders, cancer of the stomach will lose its now appalling aspects.

The technical difficulties of resection of the stomach for cancer increase with the extent of the local growth and the localization of the growth nearer the cardia; and with this, of course, the postoperative mortality increases also. In addition, when the general condition of the patient is depressed by starvation, with the concomitant anemia and acidosis, postoperative deaths from pneumonia, embolism and anuria are more frequent.

Of the three cases apparently cured, the duration of continuous symptoms was eight months, eleven months and eleven months. In two cases, the lesion was at the pylorus, in one on the lesser curvature. These cases are as follows:

Case 1 (Pathologic No. 7307).—Specimen sent to the laboratory by the operator, Dr. Marcella Hartwig, of Buffalo. The operation was performed in 1900. After the complete pylorectomy, the duodenum was sutured to a new opening in the posterior wall of the stomach—Kocher's anastomosis.

The patient was a white woman aged 50; there had been definite continuous gastric symptoms for eight months with gradually increasing symptoms of stenosis and loss of weight. At the examination there was a movable, palpable mass in the region of the pylorus. At operation there were no adhesions and no enlarged glands. There was no difficulty in the resection and suture.

Figure 1 pictures the external view of the mass removed, and Figure 2 the surface view of the longitudinal section. One can easily see the uninvolved duodenum and stomach to each side of the tumor. The tumor is a somewhat fungous mass, but it has not infiltrated through the submucosa. Microscopically (Fig. 3) it is an adenocarcinoma.

I am informed by Dr. Hartwig that this patient died seven years after operation with symptoms of abscess of the kidney and no evidence of recurrence of the carcinoma.

Case 2 (Pathologic No. 8679).—The operation was performed by Dr. Miller, the resident surgeon of the Johns Hopkins Hospital, Jan. 4, 1908. The operation consisted of resection of the pyloric end of the stomach, closure of the duodenum and stomach, and a posterior gastro-enterostomy, a method known in the literature as Billroth's II.

Figure 4 illustrates the surface view of the removed portion of the stomach. The lesion is a large ulcer with the typical elevated edge more characteristic of cancer than ulcer. Figure 5 shows a longitudinal section through stomach and ulcer, and one can see that cancer has infiltrated to the peritoneal coat. One gland at this point was involved; other glands were not microscopically affected. Figure 6 is a photomicrograph of a section through the ulcer. The glandular arrangement is still preserved in the adenocarcinoma.

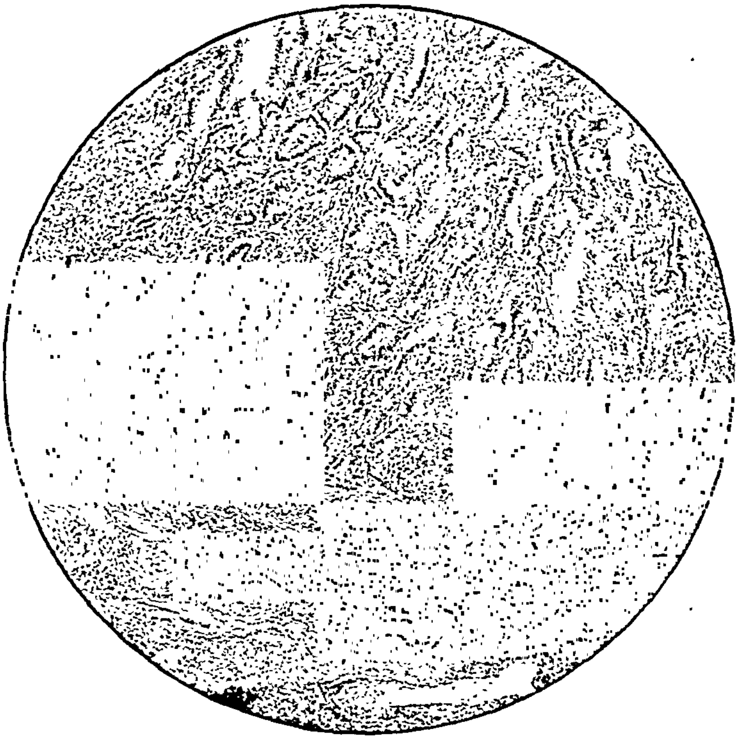

Fig. 9 (Case 3).—Fungous ulcer.

The patient was a white woman aged 43; for eleven months there had been continuous discomfort in the epigastrium, increased by eating solid food. The distress was so great that she consulted a physician within five months. On restricted diet she had been more comfortable. The patient had vomited three times—the first attack of vomiting was two months before admission. With her inability to eat without discomfort she had lost weight and strength. At the examination the most conspicuous finding was a mass; gastric lavage demonstrated residuum, but no blood. The residuum was rather slight. Hydrochloric acid was absent, total acidity 13. Apparently it was the palpable mass which urged operation.

At operation the mass occupied the lesser curvature. It was freely movable, and there were no adhesions.

This patient lived in comfort about seven years. She was readmitted to the Johns Hopkins Hospital in February, 1915, with a huge pelvic tumor of which there had been symptoms but a few months. This patient died within a few weeks in the hospital, and the necropsy demonstrated a primary adenocarcinoma of the body of the uterus with involvement of the ovaries, broad ligaments and glands. There was no evidence of carcinoma in the area of the stomach, and every evidence that the present disease had no relation to the cancer of the stomach removed seven years before.

Case 3 (Pathologic No. 10763).—In this case the operation was performed at St. Agnes Hospital by Dr. Bloodgood, Aug. 11, 1910. There was a movable, nonadherent mass at the pylorus. After the simple resection the duodenum was sutured to the stomach after Kocher's method.

Figure 7 shows the external surface of the mass resected; the normal duodenum and stomach on each side of the tumor are clearly seen.

Figure 8 pictures a longitudinal section. The tumor begins at the pylorus; it is a somewhat fungous ulcer, and has not infiltrated through the peritoneum, as shown in Figure 9, a photomicrograph.

This patient was a white man aged 55; his symptoms began eleven months before operation; at first simple discomfort in the epigastrium after eating. In three months there were definite symptoms of stenosis, recognized by his physician, Dr. Wertz of Hagerstown, Md., but the patient refused operation until August. At that time he was greatly emaciated, anemic, and the stenosis was almost complete. Fortunately the Kocher anastomosis worked well, and the patient could be fed immediately after operation.

At this time, May, 1915, there is no evidence of recurrence.

Albucasis — 1000 A.D.—Albucasis insisted that for successful surgery a detailed knowledge of anatomy was, above all, necessary. He said that the reason why surgery had declined in his day was that physicians did not know their anatomy. The art of medicine, he added, further required much time. Unfortunately, to quote Hippocrates, there are many who are physicians in name only, and not in fact, especially in what regards surgery. He gives some examples of surgical mistakes made by his professional brethren that were particularly called to his attention. They are the perenially familiar instances of ignorance causing death because surgeons were tempted to operate too extensively. His description of the procedure necessary to stop an artery from bleeding is an interesting example of his method of teaching the practical technic of surgery. Apply the finger promptly on the opening of the vessel and press until the blood is arrested. Having heated a cautery of the appropriate size, take the finger away rapidly and touch the cautery at once to the end of the artery until the blood stops. If the spurting blood should cool the cautery, take another. There should be several ready for the purpose. Take care, he says, not to cauterize the nerves in the neighborhood, for this will add a new ailment to the patient's affection.—Walsh: Makers of Medicine.

[illegible] acid [illegible] associat [illegible] to th [illegible] In [illegible] chiefl [illegible] perfo [illegible] year the c [illegible] our clin [illegible] The previou [illegible] as to attrac [illegible] perforation occurred, t [illegible] intermittent [illegible] disturbances followed by [illegible] sometimes [illegible] length, in which they were fairly well. The symptoms complained of were characteristic — hyperacidity, hypersecretion, *hunger pain*, food relief and, in the later stages, the phenomena which accompany obstruction.

These various findings were most interesting and led promptly to a more careful examination [illegible] similar cases in [illegible] we had been [illegible] ating for so-called pyloric obstruction, supposedly due to ulcers of gastric origin. The investigation showed that a high percentage of the ulcers believed to be pyloric were in reality in the first portion of the duodenum.

Fig. 1.—Types of pyloric vessels in relation

In 1904 I reported to the American Surgical Association fifty-eight cases of undoubted duodenal ulcer in which C. H. Mayo and I had operated.[2] Even at that time we had no conception of the frequency with which duodenal ulcer had occurred. This is shown by a comparison of the statistics of cases in which operation was done in our clinic as noted at subsequent dates: In 1904 the relation of gastric ulcer to ulcer of the duodenum was: gastric 73 per cent., duodenal 27 per cent.; in 1907, gastric 52 per cent., duodenal 48 per cent.; in 1910, gastric 35 per cent., duodenal 65

Gastric [illegible] of the stomach is not often [illegible] as in this [illegible] in connection with the [illegible] hypertrophy and edema. [illegible] of the duodenum are [illegible] more often on the [illegible] just below the pylorus [illegible] to involve the pyloric [illegible] and obstructive but [illegible] that they are duodenal. [illegible] and those which bleed excessively are more often situated on the posterior wall, the callus sometimes extending into the head of the pancreas. Such ulcers may be concealed from view underneath the pyloric ring, but seldom involve the gastric mucosa. When an ulcer is situated on the posterior wall, a superficial contact ulcer will usually be found opposite on the anterior wall. The *mucosa* of the duodenum is thin, smooth and granular, and chronic duodenal ulcers may not therefore have the characteristics we have learned to expect from experience with gastric ulcers. I have excised a number of duodenal ulcers in which [illegible] tissue in the submucosa [illegible] evidence of localized peri- [illegible] was a mere slit or dimple [illegible] discolored, "moth-eaten" [illegible] the type of ulcer which [illegible] unless there is a *corn-like* [illegible] the ulcer, in which case it [illegible] and callus characteristic of

4. Brinton: On th [illegible] of the Stomach, [illegible]

Without going further into the question of the relative frequency of gastric and duodenal ulcers, it may easily be seen that the clinical and postmortem demonstration of peptic ulcers has been, to say the least, misleading. The Germans, who were slow to investigate duodenal ulcer, were the greatest comfort to those who did not believe that duodenal ulcer occurred with any degree of frequency. A celebrated German surgeon said in explanation: "We relied too much on the supposed knowledge of the gastro-intestinal specialist; he was so positive that we really thought he knew."

The change in opinion in Germany within the last two years has been very remarkable and is best demonstrated by Kümmel's[6] statistics of the Eppendorf Hospital. Quoting from his recent paper: "It is not uninteresting for me to explain to you how in the relatively short time, especially within the last few years, the number of duodenal ulcers has increased among us and how a notable gain in the *actual objective material* in our *pathologic institutes has been brought to light by Fraenkel.*"

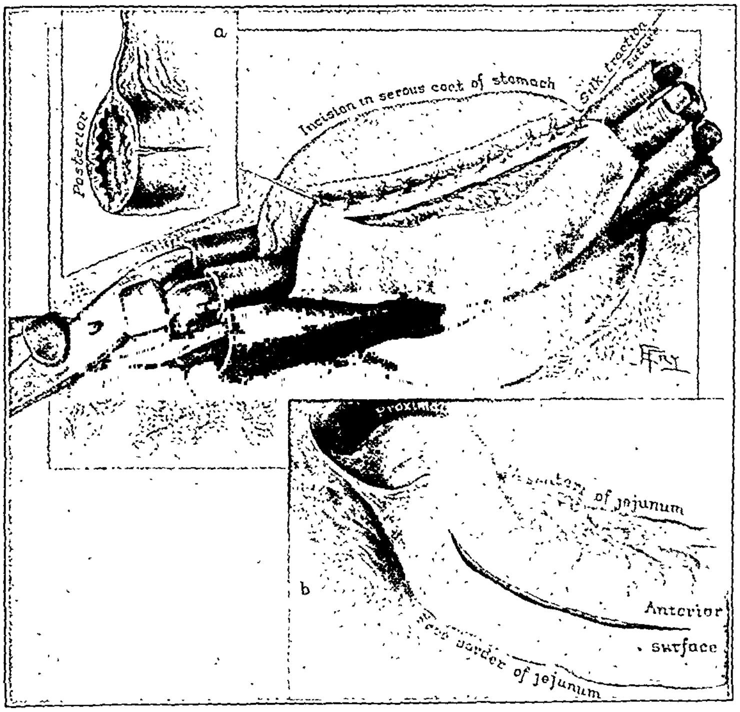

Fig. 2.—Interrupted seromuscular sutures, posterior row, in place. Peritoneal and muscular coats of jejunum incised to mucosa. Dotted line on stomach indicates line of incision. *a*, line of incision in jejunum, not opposite mesentery but on the upper left side. *b*, line of incision in jejunum.

Of equal significance is the work of Schrijver[7] of Amsterdam who shows the same striking increase in

RELATIVE NUMBERS OF GASTRIC AND DUODENAL ULCERS (KUMMEL)

From 1897 to end of 1911, 191 gastric ulcers to 16 duodenal.
1912, 10 gastric ulcers to 7 duodenal.
1913, 11 gastric ulcers to 30 duodenal.
First three months 1914, no gastric ulcers to 12 duodenal.

the recognition of duodenal ulcer. Those experiences can be multiplied from all the advanced European clinics. The clinical frequency of duodenal ulcer has been demonstrated by exact methods under the sense of sight in the operating room.

Wilkie,[8] of the Royal Infirmary of Edinburgh, has found forty-one (9.9 per cent.) duodenal ulcers in 490 postmortems. In only six cases had antemortem diagnoses been made; in these operations had been done. Wilkie quotes Gruber that 75 per cent. of duodenal ulcers found after death had not been diagnosed during life.

The experimental production of gastric and duodenal ulcers as yet appears to have little bearing on chronic callous ulcer. There is a type of acute ulcer probably toxic in origin which gives rise to sudden severe symptoms often followed by perforation or hemorrhage. These patients left untreated either die or completely recover within a few weeks. The ulcers are multiple; there is no callus and several ulcers may perforate simultaneously. So far as I have been able to observe, experimental ulcers belong to this class and are of very little value in determining the character and position of the chronic callous ulcer of the duodenum. The latter are usually single, seldom begin with an acute attack, and as a rule the earlier symptoms are less severe than the later ones.

It is interesting to speculate as to what diagnoses were made in the cases of duodenal ulcers prior to our present knowledge. It is altogether probable that a large percentage of chronic duodenal ulcers were not diagnosed at all. Some of them were believed to be gastric ulcers.

A high percentage of acute perforations were believed to be acute appendicitis since the fluids quickly gravitate into the right iliac fossa, and the appendix as well as the surface of the intestine early shows marked evidences of peritonitis. Ten years ago it was taught that an appendix apparently normal in its mucosa, under certain conditions, permitted bacteria to pass into the peritoneal cavity, causing septic peritonitis. The mistake was often not discovered even at operation and the death of the patient came after extensive peritoneal involvement had obscured the site of perforation in the duodenum sufficiently to prevent recognition. The experience of the Massachusetts General Hospital as reported by Codman[9] is instructive in this respect.

CHRONIC DUODENAL ULCER *

WILLIAM J. MAYO, M.D.
ROCHESTER, MINN.

In the presidential address delivered before the American Surgical Association in 1900, Dr. Robert F. Weir[1] called attention to the surgical possibilities of ulcer in the duodenum. In his masterly presentation of the subject he dealt chiefly with the acute cases, especially those in which perforation had taken place. Within the following year the condition was recognized in examining patients in our clinic and several patients were operated on. The previous history in each case was so distinctive as to attract attention at once. Before the perforation occurred, the patients suffered from intermittent digestive disturbances followed by intervals, sometimes of great length, in which they were fairly well. The symptoms complained of were characteristic — hyperacidity, hypersecretion, hunger pain, food relief and, in the later stages, the phenomena which accompany obstruction.

These various findings were most interesting and led promptly to a more careful examination in similar cases in which we had been operating for so-called pyloric obstruction, supposedly due to ulcers of gastric origin. The investigation showed that a high percentage of the ulcers believed to be pyloric were in reality in the first portion of the duodenum.

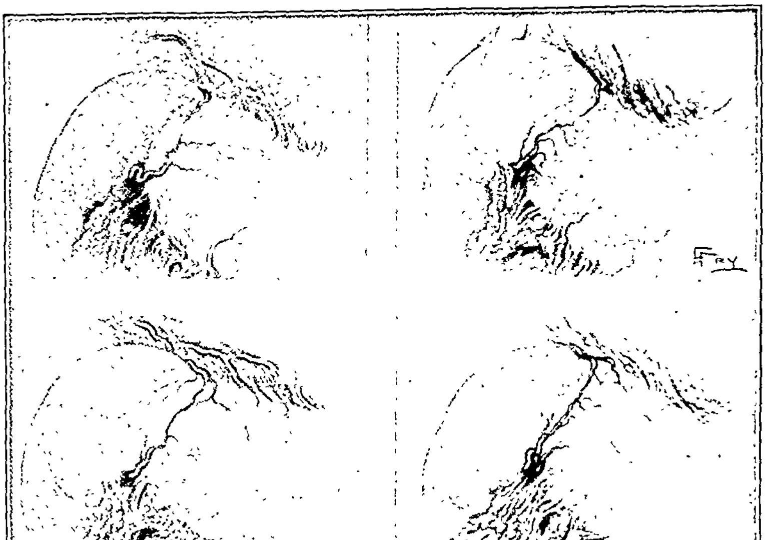

Fig. 1.—Types of pyloric vessels in relation to the location of the pylorus.

In 1904 I reported to the American Surgical Association fifty-eight cases of undoubted duodenal ulcer in which C. H. Mayo and I had operated.[2] Even at that time we had no conception of the frequency with which duodenal ulcer had occurred. This is shown by a comparison of the statistics of cases in which operation was done in our clinic as noted at subsequent dates: In 1904 the relation of gastric ulcer to ulcer of the duodenum was: gastric 73 per cent., duodenal 27 per cent.; in 1907, gastric 52 per cent., duodenal 48 per cent.; in 1910, gastric 35 per cent., duodenal 65 per cent.; in 1914, gastric 27 per cent., duodenal 73 per cent.

Our work during this early period was greatly stimulated by the splendid contributions of Robson and Moynihan, whose observations and results agreed with those in our clinic. The fact that surgeons working simultaneously in different countries should come to the same conclusion seemed very significant.

The idea that duodenal ulcer was more frequent than gastric ulcer was slowly evolved. Surgeons investigating conditions at the operating table were more readily convinced than physicians working along the lines of specialized gastro-enterology. A prominent specialist in gastro-intestinal diseases once asked, "How is it possible that you, a general surgeon, see so many of these cases while I who am devoting all my time to this work see so few?" I could only answer, "The thickness of the abdominal wall prevents you from seeing them."

Postmortem statistics have been and are still quoted in opposition to the view that duodenal ulcer is a frequent condition. For example, the statistics of Rokitansky,[3] master pathologist, were published in 1839. Brinton,[4] whose statistics are so readily quoted on every occasion, published his work in 1857. These did not represent Brinton's personal observations, but what he had gleaned from postmortem records obtained from diverse sources previous to that time and did not necessarily represent facts but their interpretation in the light of the time when the statistics were compiled. The statistical method of settling such questions is none too good at best and when the statistics are from fifty to seventy-five years old they can hardly be accepted as representing modern thought on the subject of gastric and duodenal ulcers.

The methods of clinical study have been even more chaotic. For example, compare the clinical diagnoses of gastric ulcer on admission to the hospital with the necropsy findings ten years ago. Take three hospitals in Philadelphia: University Hospital, clinical diagnosis of gastric ulcer 0.48 per cent.; Pennsylvania Hospital,

clinical diagnosis 0.13 per cent.; Blockley Hospital, as the result of necropsy findings giving 1.42 per cent. of gastric ulcer (Francine[5]). In other words, in two hospitals of exactly the same character in the same city ulcer was diagnosed clinically nearly four times as often as in the other, while both fall short of the actual postmortem findings in the third hospital from three to eleven times. Duodenal ulcer was seldom mentioned as a clinical or necropsy finding. Francine says: "We cannot base accurate or conservative conclusions on data obtained from clinical observation."

Without going further into the question of the relative frequency of gastric and duodenal ulcers, it may easily be seen that the clinical and postmortem demonstration of peptic ulcers has been, to say the least, misleading. The Germans, who were slow to investigate duodenal ulcer, were the greatest comfort to those who did not believe that duodenal ulcer occurred with any degree of frequency. A celebrated German surgeon said in explanation: "We relied too much on the supposed knowledge of the gastro-intestinal specialist; he was so positive that we really thought he knew."

The change in opinion in Germany within the last two years has been very remarkable and is best demonstrated by Kümmel's[6] statistics of the Eppendorf Hospital. Quoting from his recent paper: "It is not uninteresting for me to explain to you how in the relatively short time, especially within the last few years, the number of duodenal ulcers has increased among us and how a notable gain in the *actual objective material* in our *pathologic institutes has been brought to light by Fraenkel.*"

Of equal significance is the work of Schrijver[7] of Amsterdam who shows the same striking increase in

RELATIVE NUMBERS OF GASTRIC AND DUODENAL ULCERS (KUMMEL)

From 1897 to end of 1911, 191 gastric ulcers to 16 duodenal.
1912, 10 gastric ulcers to 7 duodenal.
1913, 11 gastric ulcers to 30 duodenal.
First three months 1914, no gastric ulcers to 12 duodenal.

the recognition of duodenal ulcer. Those experiences can be multiplied from all the advanced European clinics. The clinical frequency of duodenal ulcer has been demonstrated by exact methods under the sense of sight in the operating room.

Wilkie,[8] of the Royal Infirmary of Edinburgh, has found forty-one (9.9 per cent.) duodenal ulcers in 490 postmortems. In only six cases had antemortem diagnoses been made; in these operations had been done. Wilkie quotes Gruber that 75 per cent. of duodenal ulcers found after death had not been diagnosed during life.

The experimental production of gastric and duodenal ulcers as yet appears to have little bearing on chronic callous ulcer. There is a type of acute ulcer probably toxic in origin which gives rise to sudden severe symptoms often followed by perforation or hemorrhage. These patients left untreated either die or completely recover within a few weeks. The ulcers are multiple; there is no callus and several ulcers may perforate simultaneously. So far as I have been able to observe, experimental ulcers belong to this class and are of very little value in determining the character and position of the chronic callous ulcer of the duodenum. The latter are usually single, seldom begin with an acute attack, and as a rule the earlier symptoms are less severe than the later ones.

It is interesting to speculate as to what diagnoses were made in the cases of duodenal ulcers prior to our present knowledge. It is altogether probable that a large percentage of chronic duodenal ulcers were not diagnosed at all. Some of them were believed to be gastric ulcers.

A *high* percentage of acute perforations were believed to be acute appendicitis since the fluids quickly gravitate into the right iliac fossa, and the appendix as well as the surface of the intestine early shows marked evidences of peritonitis. Ten years ago it was taught that an appendix apparently normal in its mucosa, under certain conditions, permitted bacteria to pass into the peritoneal cavity, causing septic peritonitis. The mistake was often not discovered even at operation and the death of the patient came after extensive peritoneal involvement had obscured the site of perforation in the duodenum sufficiently to prevent recognition. The experience of the Massachusetts General Hospital as reported by Codman[9] is instructive in this respect.

I shall not go into the question of the etiology of duodenal ulcer. It is quite evident that the same causes which produce gastric ulcer produce duodenal ulcer. The thrombosis and embolism theory, the nerve theory, the bacterial theory, the mechanical theory, and the erosion theory all have their advocates. The latest recruit to the infection theory is Rosenow,[10] whose splendid investigation as to the relation of the streptococci in the terminal capillaries of the mucosa to ulcer of the stomach and duodenum is most illuminating. This theory is borne out by the edematous inflammatory character of the ulcerous duodenum found when operating during an exacerbation of the symptoms and further by the fact that following acute perforation of an ulcer, if the patient is so fortunate as to recover, the ulcer heals as though some harmful agent had been extruded. If later other symptoms are manifested they are due to the obstruction or deformity which follows in the wake of ulcer.

Fig. 3.—Upper figure shows through and through catgut suture of posterior wall before opening the mucosa. Dotted line shows where mucosa is divided. Lower figure shows mucosa flaps stitched across with catgut suture.

One possible source of injury to the mucosa of the lesser curvature of the stomach and duodenum which may have some bearing on the etiology of peptic ulcer and also to cancer of the stomach is hot drinks. Solid food is masticated in the mouth and then passes into the fundus of the stomach where it is retained during the early period of gastric digestion. If the food is very hot, it is more or less cooled in the act of mastication, but drinks are taken into the stomach much hotter than can be borne in the mouth. Anyone taking the trouble to experiment will probably find they have been in the habit of swallowing fluids much too hot to be held in the mouth comfortably. The stomach and duodenum give little immediate indication that the fluid is too hot. These hot fluids are carried rapidly along the lesser curvature into the duodenum to the exact situation in which the majority of ulcers are found, possibly removing the protective mucus which prevents autodigestion and which may result in chronic irritation. Extremely cold drinks may have the same effect.

The experiments of Jefferson[11] as to the canalis gastricus have shown that liquids, when taken in considerable quantity, pass rapidly along the lesser curvature and into the duodenum without mixing with the food mass in the fundus.

The pyloric veins are most valuable in differentiating gastric from duodenal ulcer. A short, stumpy vein comes out from above and another from below the pylorus, sometimes sending a small branch across the top of the pylorus (Fig. 1). These veins are quite unlike the vessels of other situations of the stomach and when their peculiarities have once caught the eye they serve readily to locate the pyloric ring. Gastric ulcer in the pyloric end of the stomach is not often mistaken for duodenal ulcer but for cancer, as in this situation a tumor usually forms in connection with the ulcer as the result of muscular hypertrophy and edema.

The large majority of ulcers of the duodenum are located in the first 1½ inches, more often on the anterior wall. A number begin just below the pylorus and at first glance they appear to involve the pyloric ring, especially when extensive and obstructive but careful examination will show that they are duodenal. The deeper, larger ulcers and those which bleed excessively are more often situated on the posterior wall, the callus sometimes extending into the head of the pancreas. Such ulcers may be concealed from view underneath the pyloric ring, but seldom involve the gastric mucosa. When an ulcer is situated on the posterior wall, a superficial contact ulcer will usually be found opposite on the anterior wall. The mucosa of the duodenum is thin, smooth and granular, and chronic duodenal ulcers may not therefore have the characteristics we have learned to expect from experience with gastric ulcers. I have excised a number of duodenal ulcers in which there was considerable scar tissue in the submucosa and muscularis and marked evidence of localized peritonitis; yet the actual ulcer was a mere slit or dimple surrounded by an eroded, discolored, "moth-eaten" patch of mucosa. This is the type of ulcer which occurs on the anterior wall unless there is a corn-like thickening over the top of the ulcer, in which case it will have the size, depth and callus characteristic of gastric ulcer.

Ulcers may exist in the duodenum at any point above the opening of the common duct or even down as low as the opening. I have observed three cases marked by repeated hemorrhage in which the ulcer involved the papillae of the common duct on its superior surface.

A high percentage of duodenal ulcers perforate the mucosa and muscularis to the peritoneal coat. These are classified as chronic perforations; complete perforation having been prevented by thickening of the peritoneum or adhesions to the gallbladder, omenta, suspensory ligament of the liver, etc. Many times an acute perforation actually takes place with the recovery of the patient, since the opening may be small, allowing but little fluid to escape and that fairly sterile. In such cases patients have a localized peritonitis with extreme pain lasting for several days and then make a spontaneous recovery. I have explored a number of such cases during an attack of acute localized peritonitis and have discovered the duodenal opening which had been spontaneously closed by adhesions. Occasionally absorption of the escaping products is incomplete and a phlegmon, usually underneath the liver, forms which can be opened and drained. If this is done gently the original source of leakage in the duodenum will probably not be reopened.

[11] Jefferson: Jour. Anat. and Physiol., 1915, xlix, 165.

The symptomatology of duodenal ulcer is so well known that in the typical cases failure of diagnosis should not occur. The hunger pain and food relief, hyperacidity and hypersecretion and, in the later stage, obstructive phenomena, leave little doubt as to the character of the lesion. Failure in differential diagnosis may be due to accompanying diseases of the gallbladder, appendix, etc., which occur in about 16 per cent. In our experience, actual hemorrhage takes place in somewhat less than 25 per cent. of the cases, but if one is satisfied to ask the patient questions and accept doubtful evidence as to black stools, etc., this percentage can be increased to as much as 70 per cent. We have not found occult blood a reliable symptom and do not attach a great deal of importance to it. I say this with some reluctance, since many diagnosticians for whom I have the highest respect believe that it is a diagnostic sign of very great importance.

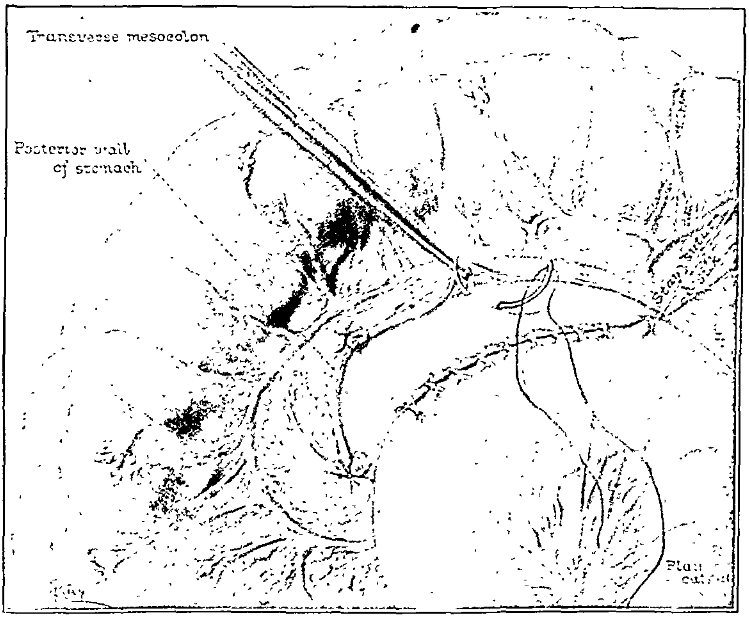

Fig. 4.—Stay suture distal to the anastomosis and suture of margin of the opening in mesocolon to stomach. Note that stomach hangs below transverse mesocolon making a funnel.

The Roentgen ray is a very important and increasingly valuable means of diagnosis. By this means, when taken in conjunction with the clinical history, a diagnosis can be made in approximately 95 per cent. of cases.

The physical examination, including the use of the stomach tube, is important as evidencing hypersecretion and food retention, tumor, visible peristalsis, etc. Laboratory diagnosis, that is, microscopic and chemical examination of gastric contents, has some value but is largely of a corroborative nature and has been very greatly overestimated. Dividing into four groups the means of diagnosis, the history is of first importance, the Roentgen ray second, the physical examinations (stomach-tube findings, etc.) third and the purely laboratory findings a poor fourth.

One of the most curious phenomena connected with duodenal ulcer is its intermittency. The disease usually begins in young males (eighty-three males to seventeen females); after a period of some weeks of symptoms there is a cessation more or less complete and the patient goes for months without any knowledge of his ailment. Then the symptoms recur and after a time the usual remission takes place. This may go on for years until finally obstruction supervenes and the symptoms become more or less constant, although the gastric muscles may by hypertrophy become competent to overcome considerable obstruction, in this respect acting quite like the heart in valvular disease — periods of competency followed by periods of incompentency.

A study of the history of the natural course of chronic duodenal ulcer makes the prospects of permanent cure by medical means open to question. I have seen a number of so-called "medical cures" and have not been able to determine that there was any material difference between them and the spontaneous remissions. The ulcer, as far as Roentgen-ray evidence is concerned, shows no physical change in the period of improvement. In operating during this period, no sign of healing is found. By means of alkalies, restricted diet, frequent feeding, largely milk and cream, whereby chemical corrosions are controlled, patients with chronic duodenal ulcers are relieved; a remission of the symptoms being secured and maintained for an indefinite length of time. But such patients cannot be looked on as cured unless they can go back, without a recurrence of trouble, to the regular diet of the grade and character obtainable by the average man. As a matter of fact, relapse usually takes place under such circumstances and the dangers of perforation and hemorrhage are ever present.

Other things being equal, after failure of reasonable medical treatment, patients with unhealed chronic duodenal ulcer should be considered surgically. To evade operation in the unhealed case is, I believe, a risk not commensurate with the value received from operative interference. No class of patients gives better results following surgical intervention.

A recurrence of symptoms after operation is most often due to defective surgical technic, usually a gastrojejunal-stitch ulcer occurs caused by the use of continuous silk or linen threads. Such sutures may hang, causing ulceration and trouble for months or years. The stitch ulcer produces the same symptoms as the original ulcer: hunger-pain, food-relief, hypersecretion, and hyperacidity. I have reason to believe that many of the poor results following gastro-enterostomy are the sequelae of sutures which have finally passed out.

The clinical course of stitch ulcers is quite typical. The patient is operated on for chronic duodenal ulcer and gastro-enterostomy is done. He is relieved and for from three to six months feels fairly well; he then begins to develop the former symptoms and it is supposed that the original ulcer has recurred. In the course of some weeks or months, about the time the suture finally separates, gradual improvement takes place.

Recently a large number of articles have appeared dealing with the necessity of closure of the pylorus to prevent food from passing down into the ulcerated area. The evidence as to the necessity of this procedure is not clear. Stitch ulcers and improperly selected patients are responsible for the recurrence of the symptoms in most instances. We have not found that the patients in whom the pylorus was blocked have in any way had results superior to those in whom it was not blocked following simple gastro-enterostomy. If perforation is impending I think it wise to block the pylorus and cover the ulcer; if there have been hemorrhages this should be done and the vessels in the vicinity of the ulcer carefully tied. But there is no evidence that the routine blockage of the pylorus is advisable or necessary, and if it cannot be done without additional risk, I think perhaps it had better be left undone.

The enthusiastic operator who has made gastro-enterostomies because of symptoms or for supposititious ulcers which he believed he could see or feel has greatly harmed gastric and duodenal surgery. In our clinic more than 100 unnecessary gastro-enterostomies have been cut off because of secondary complications such as chronic bile regurgitation, etc. Fourteen of these were our own patients operated on in the early period when it was not understood that a patient should not be operated on unless the ulcer could be actually demonstrated. At the time of these secondary operations careful search did not reveal evidence that ulcer of the stomach or duodenum had ever existed. Now that blockage of the pylorus has become popular, an alibi is established in advance inasmuch as the scar made by the ultimate passage of the suture into the gastro-intestinal lumen creates a reasonable doubt as to whether the scar is due to healed ulcer or to the thread. In other words, pyloric blockage often establishes false testimony.

In the large majority of cases gastro-enterostomy is the ideal operation for duodenal ulcer with or without infolding the ulcer (Figs. 2, 3, 4). In selected cases, excision of the ulcer in conjunction with the gastroduodenostomy of Finney is the operation of choice. In those rare cases in which true jejunal ulcer forms following gastro-enterostomy, the jejunal ulcer should be excised, the stomach and jejunal openings closed and the Finney operation done after cutting off the gastro-enterostomy. Following surgical intervention, the patient should be under good medical advice until permanent cure is assured.

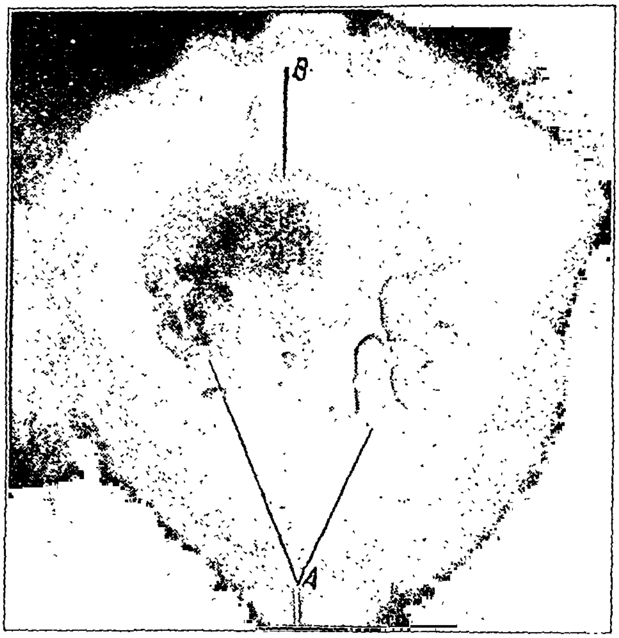
VESICULAR ALBUMINURIA

WILLIAM T. BELFIELD, M.D.

Professor of Genito-Urinary Surgery, Rush Medical College

CHICAGO

For days after the seminal vesicles are filled with collargol solution through an incision into the vas (vasostomy), this black substance appears in the urine, for the peristaltic contractions of the vesicles press their contents into the prostatic urethra and thence into the bladder. If the patient pass the first half-ounce of urine into a small glass, the bulk of the urine into a large glass and the last ounce or thereabouts, into a third, it will be seen that the first half-ounce has the largest percentage of collargol (deepest color), the second the least, and that the third is usually intermediate in blackness. It is obvious that not merely collargol, but also the natural contents of the vesicles in health and disease, must at times be discharged by peristalsis into the prostatic urethra, thence to flow into the bladder and be voided with the urine. The vesicular contents normally include nucleoproteins, albumoses and globulins, all of which are precipitated by nitric acid, though only the globulins are coagulated by heat. While the percentage of these in the urine is commonly minute, yet it becomes at times sufficient to give distinct precipitates by the usual tests. Diseased vesicles furnish globulin, albumin, pus and blood, all of which may be diffused through the urine in the bladder.



Roentgenogram made an hour after filling with collargol solution, and fifteen minutes after bladder had been irrigated and then filled with air. *A*, seminal vesicles; *B*, pool of collargol solution in the bladder, expressed from the vesicles by peristalsis.

How shall we distinguish vesicular from renal albuminuria? Not by the presence or absence of spermatozoa, as was formerly supposed, because the vesicular contents are albuminous even when the sperms are imprisoned in the testicles by bilateral epididymitis or vasectomy. Catheters in both ureters furnish urine free from vesicular contamination, but ureter catheterism is not generally practiced. The three-glass method, already described, furnishes a simple means of differentiation: Albuminous substances furnished to the urine by the vesicles are unevenly distributed, the precipitates by heat and nitric acid being distinct in the first half-ounce and the last ounce of urine, less distinct or even absent in the intermediate ounces, while albumin of renal origin is evenly diffused throughout.

In a recent case of intermittent albuminuria, it was found that the first half-ounce and last ounce of urine usually contained albumin and microscopic blood, while the intermediate portion was commonly free from both. The emitted semen contained macroscopic blood. Catheters introduced into the ureters yielded urine free from blood and albumin. During several months his prostate and vesicles were frequently massaged by Dr. Wishard in Indianapolis and by myself, without appreciable effect. In June, 1914, I irrigated his right vesicle with peroxid through a vasostomy, and filled it with collargol solution; during the ensuing eleven months his semen has been free from blood and his urine from albumin.

Peristalsis of the vesicles, hitherto unrecognized, reveals a possibly frequent source of transient albuminuria without renal disease.

THE EXCRETION OF MERCURY BY THE GASTRIC MUCOUS MEMBRANE *

C. C. LIEB, M.D.
AND
G. M. GOODWIN, M.D.
NEW YORK

It has been known for a long time that mercury may be recovered from the stomach washings of patients who are under the systemic influence of this metal. The presence of mercury in the gastric contents does not depend on the method by which the drug is administered. So far as we have been able to determine, no attempt has been made to ascertain the mechanism whereby the mercury finds its way into the stomach contents. There are at least three obvious explanations. In the first place, the mercury excreted by the salivary glands may be swallowed with the saliva, or it may be that the mercury is excreted in the upper part of the duodenum and regurgitated into the stomach. In either case, the presence of the metal in the gastric contents may be regarded as a contamination. Finally, it is possible that the mercury is actually excreted by the gastric mucous membrane. Whichever explanation is correct, the presence of mercury in the gastric lumen is important, for when the drug is passed on into the small intestine, it is again absorbed.

This cycle of absorption, excretion and reabsorption may explain the persistent systemic action of mercury, and probably accounts for the prolonged stay of the metal in the organism. On the other hand, the cycle may be a real danger in patients who have taken large doses of mercuric chlorid either accidentally or with suicidal intent. In fact, Lambert and Patterson[1] have recently urged the importance of gastric lavage as part of the routine treatment of mercuric chlorid poisoning.

At the suggestion of Professor Lambert, we undertook to determine whether the mercury found in the stomach is swallowed with the saliva or whether it is excreted by the gastric glands. The importance of clearing up this point is evident, for if mercury is of salivary origin, lavage is not so essential a part of the treatment, since the entrance into the stomach may be prevented by directing the patient to eject his saliva. If the mercury, however, is actually excreted by the gastric mucous membrane, lavage is of the utmost importance.

Three series of experiments were carried out.

In Series 1 rabbits were used. The animals were kept in clean cages for twelve hours before they were anesthetized with ethyl carbamate. The esophagus was tied off above, and a small rubber catheter was passed into the stomach through a small incision in the gullet and tied into place. By this procedure, contamination of the stomach contents by mercury of salivary origin was impossible. The mercury, in the form of mercuric chlorid, was injected subcutaneously. The animals were then placed on an electric pad and surrounded by hot water bottles. At the end of a given period the rabbits were exsanguinated and the stomach was excised and opened. The contents were removed and the mucous membrane washed with Ringer's solution. The stomach contents and the washings were then subjected to Vogel's test for mercury.[2] The results are shown in Table 1.

TABLE 1.—RESULTS IN SERIES 1

Rabbit No.	Dose mg.	Hours Between Injection and Examination	Vogel's Test for Mercury
46	20	7	Positive
74	20	4½	Positive

In Series 2, cats were employed. Anesthesia was induced by chloroform and continued with ether. The animals were then decerebrated. The further preparation was identical with the method used for the rabbits. Mercuric chlorid was injected subcutaneously.

TABLE 2.—RESULTS IN SERIES 2

Cat No.	Dose mg.	Hours Between Injection and Examination	Vogel's Test for Mercury
40	20	8	Positive
58	20	5	Doubtful
34	20	4	Positive

In Series 3, decerebrated cats were again used, but the duodenum as well as the esophagus was tied off. The mercuric chlorid was injected slowly into the jugular vein.

TABLE 3.—RESULTS IN SERIES 3

Cat No.	Dose mg.	Hours Between Injection and Examination	Vogel's Test for Mercury
68	20	8	Positive
79	15	6	Positive
83	15	6	Positive
102	15	4	Positive
91	15	3	Doubtful
76	15	2	Negative
84	15	1½	Negative

In a number of cases the urine and stools were also examined for mercury. The metal was found in the urine within two hours after its administration and within four and one-half hours in stools.

From these experiments it seems probable that mercury is excreted by the gastric mucous membrane, and that gastric lavage is an essential part of the treatment of mercurial poisoning.

or years. The stitch ulcer produces the same symptoms as the original ulcer: hunger-pain, food-relief, hypersecretion, and hyperacidity. I have reason to believe that many of the poor results following gastro-enterostomy are the sequelae of sutures which have finally passed out.

The clinical course of stitch ulcers is quite typical. The patient is operated on for chronic duodenal ulcer and gastro-enterostomy is done. He is relieved and for from three to six months feels fairly well; he then begins to develop the former symptoms and it is supposed that the original ulcer has recurred. In the course of some weeks or months, about the time the suture finally separates, gradual improvement takes place.

Recently a large number of articles have appeared dealing with the necessity of closure of the pylorus to prevent food from passing down into the ulcerated area. The evidence as to the necessity of this procedure is not clear. Stitch ulcers and improperly selected patients are responsible for the recurrence of the symptoms in most instances. We have not found that the patients in whom the pylorus was blocked have in any way had results superior to those in whom it was not blocked following simple gastro-enterostomy. If perforation is impending I think it wise to block the pylorus and cover the ulcer; if there have been hemorrhages this should be done and the vessels in the vicinity of the ulcer carefully tied. But there is no evidence that the routine blockage of the pylorus is advisable or necessary, and if it cannot be done without additional risk, I think perhaps it had better be left undone.

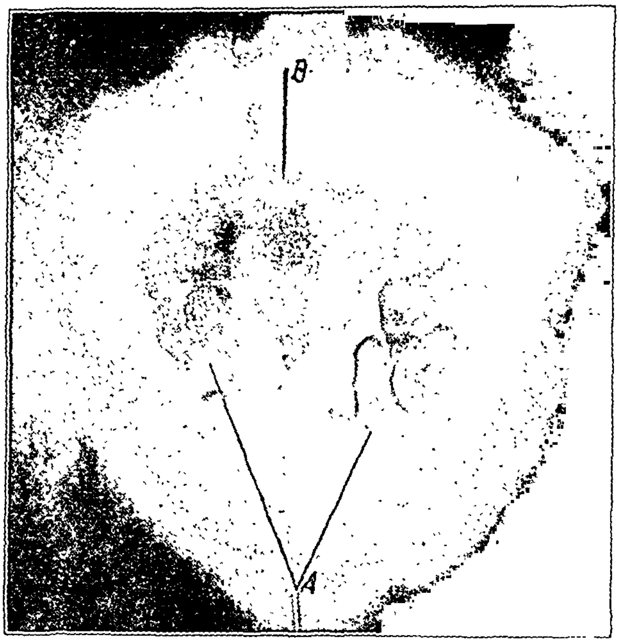
The enthusiastic operator who has made gastro-enterostomies because of symptoms or for supposititious ulcers which he believed he could see or feel has greatly harmed gastric and duodenal surgery. In our clinic more than 100 unnecessary gastro-enterostomies have been cut off because of secondary complications such as chronic bile regurgitation, etc. Fourteen of these were our own patients operated on in the early period when it was not understood that a patient should not be operated on unless the ulcer could be actually demonstrated. At the time of these secondary operations careful search did not reveal evidence that ulcer of the stomach or duodenum had ever existed. Now that blockage of the pylorus has become popular, an alibi is established in advance inasmuch as the scar made by the ultimate passage of the suture into the gastro-intestinal lumen creates a reasonable doubt as to whether the scar is due to healed ulcer or to the thread. In other words, pyloric blockage often establishes false testimony.

In the large majority of cases gastro-enterostomy is the ideal operation for duodenal ulcer with or without infolding the ulcer (Figs. 2, 3, 4). In selected cases, excision of the ulcer in conjunction with the gastroduodenostomy of Finney is the operation of choice. In those rare cases in which true jejunal ulcer forms following gastro-enterostomy, the jejunal ulcer should be excised, the stomach and jejunal openings closed and the Finney operation done after cutting off the gastro-enterostomy. Following surgical intervention, the patient should be under good medical advice until permanent cure is assured.

VESICULAR ALBUMINURIA

WILLIAM T. BELFIELD, M.D.
Professor of Genito-Urinary Surgery, Rush Medical College
CHICAGO

For days after the seminal vesicles are filled with collargol solution through an incision into the vas (vasostomy), this black substance appears in the urine, for the peristaltic contractions of the vesicles press their contents into the prostatic urethra and thence into the bladder. If the patient pass the first half-ounce of urine into a small glass, the bulk of the urine into a large glass and the last ounce or thereabouts, into a third, it will be seen that the first half-ounce has the largest percentage of collargol (deepest color), the second the least, and that the third is usually intermediate in blackness. It is obvious that not merely collargol, but also the natural contents of the vesicles in health and disease, must at times be discharged by peristalsis into the prostatic urethra, thence to flow into the bladder and be voided with the urine. The vesicular contents normally include nucleoproteins, albumoses and globulins, all of which are precipitated by nitric acid, though only the globulins are coagulated by heat. While the percentage of these in the urine is commonly minute, yet it becomes at times sufficient to give distinct precipitates by the usual tests. Diseased vesicles furnish globulin, albumin, pus and blood, all of which may be diffused through the urine in the bladder.



Roentgenogram made an hour after filling with collargol solution, and fifteen minutes after bladder had been irrigated and then filled with air. *A*, seminal vesicles; *B*, pool of collargol solution in the bladder, expressed from the vesicles by peristalsis.

How shall we distinguish vesicular from renal albuminuria? Not by the presence or absence of spermatozoa, as was formerly supposed, because the vesicular contents are albuminous even when the sperms are imprisoned in the testicles by bilateral epididymitis or vasectomy. Catheters in both ureters furnish urine free from vesicular contamination, but ureter catheterism is not generally practiced. The three-glass method, already described, furnishes a simple means of differentiation: Albuminous substances furnished to the urine by the vesicles are unevenly distributed, the precipitates by heat and nitric acid being distinct in the first half-ounce and the last ounce of urine, less distinct or even absent in the intermediate ounces, while albumin of renal origin is evenly diffused throughout.

In a recent case of intermittent albuminuria, it was found that the first half-ounce and last ounce of urine usually contained albumin and microscopic blood, while the intermediate portion was commonly free from both. The emitted semen contained macroscopic blood. Catheters introduced into the ureters yielded urine free from blood and albumin. During several months his prostate and vesicles were frequently massaged by Dr. Wishard in Indianapolis and by myself, without appreciable effect. In June, 1914, I irrigated his right vesicle with peroxid through a vasostomy, and filled it with collargol solution; during the ensuing eleven months his semen has been free from blood and his urine from albumin.

Peristalsis of the vesicles, hitherto unrecognized, reveals a possibly frequent source of transient albuminuria without renal disease.

THE EXCRETION OF MERCURY BY THE GASTRIC MUCOUS MEMBRANE *

C. C. LIEB, M.D.
AND
G. M. GOODWIN, M.D.
NEW YORK

It has been known for a long time that mercury may be recovered from the stomach washings of patients who are under the systemic influence of this metal. The presence of mercury in the gastric contents does not depend on the method by which the drug is administered. So far as we have been able to determine, no attempt has been made to ascertain the mechanism whereby the mercury finds its way into the stomach contents. There are at least three obvious explanations. In the first place, the mercury excreted by the salivary glands may be swallowed with the saliva, or it may be that the mercury is excreted in the upper part of the duodenum and regurgitated into the stomach. In either case, the presence of the metal in the gastric contents may be regarded as a contamination. Finally, it is possible that the mercury is actually excreted by the gastric mucous membrane. Whichever explanation is correct, the presence of mercury in the gastric lumen is important, for when the drug is passed on into the small intestine, it is again absorbed.

This cycle of absorption, excretion and reabsorption may explain the persistent systemic action of mercury, and probably accounts for the prolonged stay of the metal in the organism. On the other hand, the cycle may be a real danger in patients who have taken large doses of mercuric chlorid either accidentally or with suicidal intent. In fact, Lambert and Patterson[1] have recently urged the importance of gastric lavage as part of the routine treatment of mercuric chlorid poisoning.

At the suggestion of Professor Lambert, we undertook to determine whether the mercury found in the stomach is swallowed with the saliva or whether it is excreted by the gastric glands. The importance of clearing up this point is evident, for if mercury is of salivary origin, lavage is not so essential a part of the treatment, since the entrance into the stomach may be prevented by directing the patient to eject his saliva. If the mercury, however, is actually excreted by the gastric mucous membrane, lavage is of the utmost importance.

Three series of experiments were carried out.

In Series 1 rabbits were used. The animals were kept in clean cages for twelve hours before they were anesthetized with ethyl carbamate. The esophagus was tied off above, and a small rubber catheter was passed into the stomach through a small incision in the gullet and tied into place. By this procedure, contamination of the stomach contents by mercury of salivary origin was impossible. The mercury, in the form of mercuric chlorid, was injected subcutaneously. The animals were then placed on an electric pad and surrounded by hot water bottles. At the end of a given period the rabbits were exsanguinated and the stomach was excised and opened. The contents were removed and the mucous membrane washed with Ringer's solution. The stomach contents and the washings were then subjected to Vogel's test for mercury.[2] The results are shown in Table 1.

TABLE 1.—RESULTS IN SERIES 1

Rabbit No.	Dose mg.	Hours Between Injection and Examination	Vogel's Test for Mercury
46	20	7	Positive
74	20	4½	Positive

In Series 2, cats were employed. Anesthesia was induced by chloroform and continued with ether. The animals were then decerebrated. The further preparation was identical with the method used for the rabbits. Mercuric chlorid was injected subcutaneously.

TABLE 2.—RESULTS IN SERIES 2

Cat No.	Dose mg.	Hours Between Injection and Examination	Vogel's Test for Mercury
40	20	8	Positive
58	20	5	Doubtful
34	20	4	Positive

In Series 3, decerebrated cats were again used, but the duodenum as well as the esophagus was tied off. The mercuric chlorid was injected slowly into the jugular vein.

TABLE 3.—RESULTS IN SERIES 3

Cat No.	Dose mg.	Hours Between Injection and Examination	Vogel's Test for Mercury
68	20	8	Positive
79	15	6	Positive
83	15	6	Positive
102	15	4	Positive
91	15	3	Doubtful
76	15	2	Negative
84	15	1½	Negative

In a number of cases the urine and stools were also examined for mercury. The metal was found in the urine within two hours after its administration and within four and one-half hours in stools.

From these experiments it seems probable that mercury is excreted by the gastric mucous membrane, and that gastric lavage is an essential part of the treatment of mercurial poisoning.

THE ISOLATION IN CRYSTALLINE FORM OF THE COMPOUND CONTAINING IODIN, WHICH OCCURS IN THE THYROID

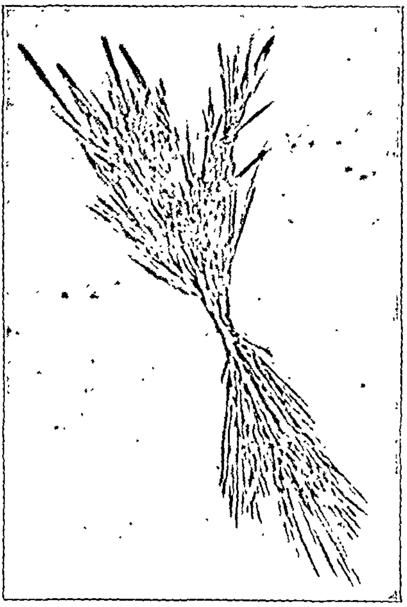
ITS CHEMICAL NATURE AND PHYSIOLOGIC ACTIVITY *

E. C. KENDALL, Ph.D.
ROCHESTER, MINN.

During the past twenty years, investigation has firmly established, among other things, the following two facts: (1) The thyroid contains some substance capable of producing marked physiologic effects, and (2) iodin is a constant constituent of normal and pathologic glands. These two facts are emphasized because most of the controversies concerning the thyroid have arisen from attempts to explain the relation between the physiologic activity and the presence of iodin.

It is obvious that no final conclusions could be arrived at until either some substance possessing physiologic activity had been isolated in pure form and shown to be a normal constituent of the gland, or until the compound containing iodin had been isolated in pure form and its physiologic activity determined.

Last December I[1] reported the separation from the thyroid of a preparation containing 60 per cent. of iodin. The present paper is a summary of the results thus far obtained. In brief, the compound containing iodin, the presence of which, as a normal constituent of the thyroid, was foretold by Baumann[2] nineteen years ago, has been isolated in pure crystalline form, and further, it has been shown that this compound is the substance in the thyroid which is responsible for the physiologic activity of the gland.[3]



Crystals of the iodin-containing compound which occurs in the thyroid.

Previous investigation has shown that the compound containing iodin is firmly held as a constituent of the thyroid proteins. Hence separation of this compound must be preceded by a breaking down of the proteins into the simpler constituents of which they are composed. Baumann attempted this hydrolysis, using 10 per cent. sulphuric acid, but no satisfactory cleavage of the molecule resulted. The hydrolysis which has been successful was accomplished with sodium hydroxid in alcohol as a medium for carrying out the process.

A large number of compounds are obtained by this splitting up of the protein, but they are separated into two groups by the addition of acid. Those compounds insoluble in acid are designated Group A, and those soluble Group B.

The total iodin in the gland is found to be divided almost equally between the two groups. By further hydrolysis of the A group the compound containing iodin has been separated in pure crystalline form. Its exact formula cannot now be stated, but it appears to be di-iodo-di-hydroxy-indol. It crystallizes in microscopic needles that melt around 220 C. It is very insoluble in alcohol, ether, water, acids and sodium carbonate. Dilute hydrochloric acid dissolves 1 part in about 200,000. It is readily soluble in dilute alkali and ammonia.

No definite substance possessing physiologic activity has been isolated from the B group, but it is known to be a complex mixture containing amino-acids. The iodin in B is in organic combination, but the nucleus to which it is attached is unknown.

The thyroid having been separated into several different constituents, it seemed desirable to test each one for its possible physiologic activity. It was found that the typical effects of administration of desiccated thyroid — a rapid increase in pulse rate and vigor, increase in metabolism with loss of weight, and increase in nervous irritability — are all produced by the A constituents.

The next step showed that in A, containing about 5 per cent. of iodin, the effects produced are directly proportional to the amount of iodin present. And finally, in the purification of A and the separation of the iodin compound in crystalline form, the same typical effects were produced through all the various stages of purity, up to and including the crystalline compound containing 60 per cent. of iodin.

In testing B for physiologic activity, it was found that no apparent effects are produced when B is given experimentally to a normal animal or human being, but that a considerable degree of activity is manifest when B is given to patients suffering from cretinism, myxedema and certain conditions of the skin. However, no toxic effects have been produced by the administration of B, even in large amount.

This nontoxic effect of B is in strong contrast to the action of A. Although both A and B contain iodin, it has been shown that the toxicity of A is in direct proportion to its iodin content, but B iodin given in equal amount produces no apparent effect.

As previous investigators have pointed out, it is not iodin per se that is necessary. This work shows that it is the iodized indol that produces the physiologic activity. The actual amount of the crystalline iodin compound necessary to produce marked effect is exceedingly small. A total of 11 mg. (one-sixth grain), given in divided doses during a period of fourteen days to a cretin weighing 40 pounds, increased the pulse rate from 90 to 140. A total of 30 mg. (one-half grain), given in divided doses over a period of eighteen days to a woman weighing 112 pounds, increased the pulse rate from 75 to 130. Not only in rate but also in apparent vigor of the beat the cardiogram of a heart, after administration of the iodin com-

[3] The physiologic activity referred to is the production of the so-called hyperthyroid symptoms, tachycardia, increase in metabolism with loss of weight and increase in nervous irritability. Some other constituents of the gland possess physiologic activity, but of minor importance.

pound, simulates a cardiogram of a patient with exophthalmic goiter.

What, then, is the relation of this iodin compound and the symptoms of exophthalmic goiter? Pathologic investigation has shown that the severity and duration of the symptoms are accompanied by definite histologic changes in the thyroid. It has been shown that in the severest forms of exophthalmic goiter the parenchyma is far more active than in the normal gland.

Analysis of 137 thyroids from exophthalmic goiter cases showed that, in those glands having a thin, watery secretion, the iodin content was very low, but as the secretion became thicker and less diffusible, the percentage of iodin increased.

These results point to two functions of the thyroid: One function is the manufacture of the iodin compound, and the other that of acting as a reservoir for this compound. We have no means at present of measuring the manufacturing capacity of the gland, but we do know that it is greatly increased in exophthalmic goiter. The reservoir capacity of the gland is obviously proportional to the iodin content. The total amount of iodin in the severest form of exophthalmic goiter averaged 7 mg., and the total iodin in glands in which the secretions had become thick and less diffusible was 35 mg. That is, the reservoir capacity had increased 500 per cent., and when it is known that 1 mg. a day of the pure crystalline iodin compound will produce marked toxic symptoms in a normal person, the important rôle played by the iodin compound in the production of symptoms of exophthalmic goiter is evident.

The separation in pure form of the iodin compound is the first necessary step in the further study, not only of pathologic conditions, but also of the normal physiology of the gland.

SUMMARY

1. By an alkaline alcoholic hydrolysis, the thyroid proteins are broken into many simpler constituents. These may be separated into two groups: the acid insoluble compounds are designated Group A; those acid soluble, Group B.

2. From Group A a pure crystalline compound, containing 60 per cent. of iodin, has been isolated. It appears to be di-iodo-di-hydroxy-indol.

3. Group B contains iodin in some unknown form of combination. It is a mixture containing amino-acid complexes and a low molecular weight.

4. Administration of A produces in the dog and in the human being a rapid increase in pulse rate and vigor, and increase in metabolism and nervous irritability. This physiologic activity is produced by the compound containing iodin in all stages of purity up to and including its crystalline form.

5. Given in excess, toxic symptoms are produced. The amount of the iodin compound required to produce toxic effects is exceedingly small.

6. In exophthalmic goiter two abnormal conditions exist. First, the secreting capacity of the gland is greatly increased and, second, the reservoir capacity of the gland is greatly decreased. The iodin compound plays an important rôle in the production of the symptoms of exophthalmic goiter.

7. The constituents of Group B produce no toxic symptoms, but in cases of cretinism, myxedema and certain skin conditions, they exert physiologic activity.

THE AIMS OF THE ASSOCIATION OF AMERICAN PHYSICIANS *

S. J. MELTZER, M.D., LL.D.
NEW YORK

It is not only customary, but it is by the order of the constitution, that the president opens the first session of the annual meeting by an address. I shall use the words of the first president of the association as a starting point for my remarks. President Delafield said:

> We want an Association in which there will be no medical politics and no medical ethics; an association in which no one will care who are the officers.

I shall deal first with the last-mentioned remark. We still do not care who the officers are. It is the prerogative and the duty of the incumbent of the office of the presidency to express his views on subjects which concern the welfare of the association. Now I wish to say that in my opinion the members of the association shall care more than they do, who are their officers, and especially who shall be their president. In the course of our existence the constitution was so amended as to invest the president with autocratic powers, while his election gradually became, by mere custom, entirely undemocratic. I presume that not many of you know the exact procedure. The five councilors fill each year the coming vacancy in their ranks. The oldest councilor becomes vice-president and then president. While the recommendations of the council are formally submitted to your vote, I am not aware that they were ever voted down. In my opinion this oligarchic form of government harbors a danger. It may readily happen that the *progressive* majority of the members will be continually governed by entrenched *regressive* elements. I do not mean to imply that we are actually confronted with such a situation; I merely wish to call your attention to the possibilities which such an anomalous situation may have in store for you. I do not wish to offer any remedial suggestions; these must come from the members.

Having served as an officer of the association for the last seven years, I am in a position to make the agreeable statement that medical politics and medical ethics still play practically no rôle in the procedure of election to membership in the association. It holds true, in general, that each year of the numerous candidates the best men are elected to fill the vacancies. But I wish to state warningly that we are not entirely free from danger. I am not afraid that we shall ever elect to membership one who was convicted for a criminal act. But avoidance of coming in collision with the criminal code or even a strict compliance with the ethical code of the American Medical Association are not unrefutable evidences of highmindedness. Commercial success in practice of medicine, social standing and social relations, manipulated publicity, the familiar principle of "one hand washes the other" and evils of a similar character are the pernicious elements which may endanger the high standard of our association. I speak not merely from theory. As president, I am entitled to express the wish that the association should comprise not only the most gifted,

Commercial success in practice of medicine, social standing and social relations, manipulated publicity, the familiar principle of "one hand washes the other" and evils of a similar character are the pernicious elements which may endanger the high standard of our association. I speak not merely from theory. As president, I am entitled to express the wish that the association should comprise not only the most gifted, most learned and best-known physicians of the land, but should consist at the same time of high-minded, clean-handed men with a tinge of idealism, I appeal to you that in proposing candidates and electing them to membership, the moral standard of the candidate should be one of the primary objects of consideration.

---

* Remarks made at the opening of the thirtieth meeting of the Association of American Physicians by its president, May 11, 1915, Washington, D. C.

The reference of the first president to politics and ethics and the historical remarks of another president reveal the cause, or rather one of the causes for the creation of this association. It was chiefly the unsatisfactory conditions which prevailed at that time in the American Medical Association that caused medical men of a higher type to form new national associations. A generation passed since the birth of this association. The change in the standard of American medicine which took place in this comparatively short span of time is marvelous indeed. Was our association an important factor in this progress? I believe that one of our presidents claimed it indeed. But justice compels me to state publicly that the credit for this achievement must be given chiefly to the great national democratic body, the American Medical Association. Since its reorganization, since the scientific part has been divorced from the politics of the Association, the character of the scientific proceedings changed completely. The purely medical work of nearly all the sections is now carried on generally by the scientifically productive, progressive medical element of the whole country which generally participates but little in the political activities of the organization. Furthermore, the new policies adopted by the recognized association undoubtedly exerted a most beneficial influence on the development of medicine in this country. I need only mention the work of the Council on Medical Education and of the Council on Pharmacy and Chemistry. The aims and the success of the last-named committee exerted even an international beneficent influence on medical therapeutics. Not the least of the merits of the regenerated American Medical Association is the high standard which The Journal is maintaining; it is undoubtedly now one of the best medical journals in the world. In this laudable work of the new American Medical Association, some of our members have taken an active part. But our association as a body cannot claim credit for the progress which was made in medical affairs of this country during the period of its existence; it was not brought about by any definite designs or policies of this association.

If the Association of American Physicians exerted an elevating influence on American medicine, it did so by its mere existence. When it was founded a generation ago, the effort was made to incorporate in it the best medical men which could be then found in the country. Since then, year by year, an effort was made to admit only those who were the best of the available material at each period. With the introduction of the institute of associate membership, a remedy was acquired to correct mistakes.

From the start our association formed a constituent part of the body known as the Triennial Congress of American Physicians and Surgeons. Like the other constituent societies, for instance, the surgical or the ophthalmologic, our association represents a certain special part of the medical practice; it represents *internal medicine.* This association, however, has one advantage over all of them. All practical medical subjects presuppose the knowledge of the pure medical sciences, for instance, physiology, pathology, bacteriology, pharmacology or hygiene. But the Association of American Physicians alone has the advantage of counting among its members invesigators of these various sciences. I say, it has the advantage; there are some among us who may not consider it an unmixed blessing.

Delafield, in the first presidential address, spoke of an association of physicians and pathologists. Osler, ten years later, added bacteriologists. We now have among our members also physiologists, pharmacologists and investigators in the fields of hygiene and preventive medicine. Permit me to define my own position as to the aim and the composition of the membership of this association. I entirely agree with the sentiment that the object of this association is, and should be, clinical medicine in both of its aspects, the scientific and the practical. Purely physiologic or chemical communications which have only a remote bearing on medicine do not belong before this forum. Neither should medical scientists whose work and interest lie at a great distance from clinical medicine be elected to membership of this association. But let me say this to you: For thirty-odd years I have been engaged in a more or less active way in the scientific as well as in the practical sides of medicine. It is my profound conviction that clinical medicine has a great future before it; but that the real success will come only from a close association of clinical medicine with the medical sciences.

The object of our association is to increase our knowledge of the intricacies of medicine, to learn from one another the new things we have unraveled and to instruct one another in the art of advancing our knowledge. That object will be best attained when the men studying the sciences of medicine and the men studying and handling diseases will come together and have a chance to be stimulated and instructed by one another. Of course both parties must be openminded, must be anxious to learn, and must have a deep interest in medicine and a full grasp of what it really means. Diseases are experiments which Nature makes on men and beasts. A mind trained in observing properly natural phenomena and studying critically experimental results is best prepared to interpret Nature's experiments, to grasp Nature's method in correcting physiologic aberration and to try courageously to improve on these methods and to discover or invent new ones. The best physician of the future will be the brainy man who spent many years in studying the methods employed in acquiring knowledge in the pure medical sciences and then in applying all his mental energies to a broad study of diseases. The field of the clinician is not confined to diagnosis and therapy alone, as was stated in one of the presidential addresses by a leading clinician. Great physicians were often also great original investigators. By diagnosis and therapy alone we would, for instance, have no knowledge of Bright's, of Graves' or of Addison's disease; we would not have known of myxedema or acromegaly. In fact, a good deal of our knowledge of the significance of the ductless glands and internal secretion was established by clinical observations, and at first even against violent opposition of some classical physiologists. An instance, illustrating the value of cooperation between clinical men and men in the medical sciences, is the discovery of the blood pressure raising principle of epinephrin by Oliver and Schäfer. It was the physician Oliver who first noticed, by insufficient methods, that the administration of extract of suprarenals seemed to increase the blood pressure. By obtaining the cooperation of the physiologist Schäfer, the subject was investigated by proper physiologic methods, and the discovery of epinephrin, which attained such great importance, was safely established.

I therefore say again that it is of great advantage to our association to have among its members investigators in the various fields of the medical sciences. Clinical medicine and medical sciences must be brought closely together and work in harmony; that will assure a steady progress of the science and practice of medicine. This union is what distinguishes our association from other societies and which gives it the right of continual existence.

Some older members complain that the papers presented at the meetings are getting above their heads. While this may be a fact, it cannot be made the basis of a complaint. The papers of the program of an annual meeting reflect in general the character of the medical studies which prevail at that period. The science of medicine is progressing. Do these members wish that our science should stop progressing as soon as they, for one reason or another, cannot follow it? The very same members who make this complaint were progressives at some time or another; otherwise they would not have become members of this association. Their work at their time was probably above the head of those who remained then behind them.

If the character of the papers on our program reflects the nature of the problems which occupied the minds of our members in the past year, the number of these papers show their intense scientific activity. A long program awaits you — and me. I shall have to be strict in enforcing the time limit to the speakers. I have the good will to be impartial and shall therefore cut short my own remarks.

PATHOLOGY OF WAR SURGERY *

BENJAMIN JABLONS, M.D.
Pathologist to the American Ambulance, Paris; Director of Laboratories, St. Francis Hospital
SAN FRANCISCO

It has been said that "Peace hath its problems no less than War." That war, however, may concentrate certain problems of peace, which are well under control in times of peace, this, and past wars have clearly demonstrated. The dangerous forces of nature, which an enlightened humanity has begun to control, come very much to the fore when humanity turns upon itself.

The object of civilized warfare has always been to render the opposing soldier a noncombatant with as little danger as possible. For this purpose we have Hague conventions, banning the use of dumdum bullets. Hague conventions take account, however, neither of the ever-present microbe nor of inclement weather, nor yet of the abuses of nature that the present methods of warfare make inevitable. It is these factors that we are fighting, and their further exposition may therefore not be out of place.

The elaborate machinery of a "Service de santé militaire" is intended to combat these dangers. An ambulance such as this is a necessary element in such a machinery, and a laboratory organization a not unimportant cog.

Our work in the department of pathology has necessarily limited itself to the problem of war surgery. The special character of the patients at the ambulance has necessitated examinations with reference to the kind of infection and the manner in which their wounds reacted to this. Our function has been, and is, to supply the microscopic eyes to the surgeons and the clinicians. It would be impossible in a short space to describe in detail each phase of the work carried out in the laboratory. I shall attempt to give only a general idea of the things we have tried to do.

The department, organized in November, has carried out to the present time, March 30, 1915, about 850 examinations, fifty necropsies and twenty biopsies. The greater part of these examinations has been chiefly that of the blood and the urine. Suspected abscesses, where generalization in the blood stream had not yet taken place, demanded an inquiry into the reacting powers of the blood. We have had 153 occasions to do this. Injuries in the neighborhood of the kidneys, possible postoperative affections of the kidneys, and infections of the kidneys in cases of spinal paralysis have required the examination of urinary specimens over 200 times.

The occurrence of tropical infections where so many of our wounded have either lived or been born, has had to be considered, this more especially where unexplained fever was present. In seven cases the malarial parasite was found to have caused the rise of temperature.

Owing to the care with which the cases have been admitted, we have fortunately been spared infectious fevers. It has been necessary twelve times only to make the differential diagnosis between typhoid fever and simulating surgical infections.

It is not uncommon for men who have healed lesions of tuberculosis, and then lead a trench life, to have these lesions develop anew. We have examined seventy-four sputums in which this possibility had to be considered.

In any community, infectious throat inflammation is an ever-present factor. Here, we have had sixty-eight examinations in which this element of diagnosis has arisen. In this, as in the other preceding cases, it is not bullets alone that slay, but bacilli that are continually adding to the dreadful toll.

It is a difficult thing for the surgeon to see the kind of bacterium with which he has to contend, with the exception of the pyocyaneous infection. The color of the pus does not sufficiently show the nature of the infecting microbe. Bacteriologic examination of the pus exuding from a wound becomes of importance for this reason. We have, in all, examined 118 wounds. Our results, as well as the results of a series of examinations conducted in the university laboratory in conjunction with the laboratory of the hospital, I shall cite below.

From the very outset we have been obliged to take into consideration the temporary nature of the hospital. To organize a complete laboratory of any permanent character meant a diversion of monies from a perhaps much more necessary aim. We have therefore contented ourselves only with the absolute essentials necessary to increase the usefulness of the laboratory to the attending surgeons. The organization of the laboratory consists at present of a series of rooms

---

* Read before the Medical Society of American Ambulance, Paris, March, 1915, and the St. Francis Hospital Clinical Society.

placed at our disposition by the kindness of the medical board and the ambulance committee. This has permitted the setting aside of: one room especially for bacteriologic investigation; one room for clinical and chemical analysis, and one room reserved exclusively for histologic examinations of tissues excised which were of a questionable nature.

The acute character of the cases in which operation was performed has made necessary only twenty-one examinations of the latter sort.

In the fifty necropsies which have been performed, the causes of death have either been secondary fatal hemorrhages from previous wounding of blood vessels reopened after a few days as a result of the sloughing of tissue, or infection of wounds of the brain, spinal cord, chest or abdomen. Under the latter heading may also be included the infections consequent to large compound fractures of either the upper or lower extremities. Tetanus was the cause of death in only two cases. Pneumonia was an occasional complicating cause after previous injury to the jaw in which swallowing had been interfered with by the swelling of the tissues of the floor of the mouth.

The vagaries of the wounding projectile were as strange as it is possible for the mind of man to conceive; and naturally so, when one considers the rain of bullets to which these men were exposed. In one case the bullet entered the left side of the abdomen at a point between the spleen and the left kidney, continued upward, and in its course injured the tail of the pancreas, traversed both walls of the stomach, and continued on through the diaphragm, finally to lodge in the muscular substance of the heart, close to the right auriculoventricular valve. This patient lived ten days after the injury. In another case the bullet had entered the left back of the chest, close to the spinal column, had ploughed its way through the lung, through the diaphragm, into the stomach and thence proceeded calmly on its way as any morsel of food. This man likewise lived a period of almost two weeks, ultimately to succumb to a suppurative pleurisy.

Cases of secondary hemorrhage have been likewise varied. Three patients — after a previous wound of either the jaw or the mouth — died of hemorrhage of the lingual artery; the vessels injured originally at the moment of the wound and controlled in the field, after several days began to bleed afresh with ultimate death from hemorrhage. These have been fortunately few. In one case of bullet wound of the jaw, the bullet passed through the back of the mastoid process, and at necropsy was found to have involved the vertebral artery. This explained the surgeon's inability to control the hemorrhage by ligating the internal and common carotid of that side. One of the rarest occurrences encountered at necropsy was a soldier with a compound fracture of the jaw, who died three days after the receipt of the injury, as a result of hemorrhage from the severed inferior dental artery. All of these conditions have been object lessons in the care and treatment of similar cases.

Injuries to the head and spinal column with a fatal outcome make up almost 30 per cent. of the fatal cases. Most of the injuries produced by the entrance of projectiles to the brain or spinal cord still resist our advanced methods of therapy. If not immediately infected, it seems a difficult thing to prevent later infection. A number of cases of gunshot wounds of the skull develop septic meningitis, caused either by the staphylococcus or the streptococcus; weeks after the wound is apparently healing satisfactorily. This is a field in which some advance is still to be looked for.

Tetanus, that dread disease of previous wars, has practically lost its terrors. The universal administration of antitetanic serum has conclusively proved its value. We have had only two deaths of this disease; one soldier had received an injection of serum immediately on his arrival at the hospital, but infection with the *Bacillus tetani* had unfortunately been too far advanced to be arrested at that time; the other patient had not received serum owing to the absence of any visible wound — the condition for which he had been admitted was that of frost bite of both lower extremities. He died of tetanus two days after admission. This demonstrates how important is the prophylactic administration of antitetanic serum in any condition in which the skin vitality may be diminished. It also demonstrates the good judgment of the surgeons in charge in insisting on the use of serum in every case admitted to this hospital — a rule which, except in the instance mentioned, has never been deviated from.

We have had seven fatal cases of gaseous gangrene infection. These have all been acute cases admitted with symptoms of fully developed gas gangrene infection, which have succumbed in a few days despite all possible efforts. I shall go more fully into this condition later.

As was to be expected, a fairly large percentage of the fatal cases was due to infection of wounds. In some of these, infection of the bone marrow was the primary cause; in others, extension of the infection into the blood vessels of the neighboring region gave rise to a purulent thrombophlebitis with spread of infection throughout the body. In a few instances, the cause of death was chronic sepsis attendant on a suppurative infection of one or more points of the body.

Of abdominal injuries which have resulted fatally, we have had only two instances. The distance of this ambulance from the front is perhaps the best explanation for its rare occurrence here.

The greatest number of fatal cases has been unpreventable. Most deaths were caused either by conditions not amenable to surgical treatment, or by the advanced state of the infection at the time of entrance. Very few were due to conditions that had not been recognized sufficiently early. Despite the greatly increased number of admissions, including cases much more severe than even in the early days of the hospital, the four deaths we have had to record since February 1 to the present date (March 30, 1915) sufficiently attest to the increased vigilance of the attending surgeons. May I be permitted to touch on the mortality of this hospital? We have had occasion in the past to realize what a frightful mortality attends surgical wounds inflicted in war time. In the total admissions, numbering well over 1,400, there have been eighty-one deaths, 6 per cent., a mortality rate which hospitals, even in peace times, might point to with a great deal of pride. How much more reason have we to be proud of so low a mortality rate with such severe, complicated injuries? We have attempted to do our little share toward helping to decrease this mortality rate by increasing the possibilities for more accurate diagnosis and adding to the indications for surgical intervention.

In research we have been able only to scratch the surface. The paucity of help and equipment is our only excuse. As previously stated, in conjunction with Dr. Huffman of the university laboratory, I have carried out bacteriologic investigations in a series of sixty-two consecutive cases. It was possible to demonstrate that of the sixty-two cases, seventeen were found harboring the *Bacillus perfringens* — in one case pure, in all other cases associated with the staphylococcus, with the streptococcus, with the *Bacillus coli*, with the pyocyaneus, and two up to the present unidentified anaerobic bacilli. The common pus producers, well known to surgeons in times of peace, have not kept their unwelcome presence from us. Staphylococcus and streptococcus have been frequent visitors. The staphylococcus has been found thirteen times; the streptococcus only six times. Clinically, old wounds showed almost a pure staphylococcus infection. When badly infected and discharging for a long period of time, the perfringens and the pyocyaneus bacilli were commonly found present. In the 118 cases in which we had occasion to carry out bacteriologic investigation in the hospital laboratory, the *Bacillus perfringens* was seen thirty-three times. On seven occasions this was the only microbe evident. These were all cases of gas gangrene, for the most part fatal.

The frequent occurrence of the *Bacillus perfringens* and other anaerobic bacilli has prompted us to carry out attempts at vaccination with the Weimberg mixed vaccine. I may safely say that it has never done harm; in cases in which the perfringens seemed to be the predominant organism, it has seemed to be of decided value. In a series of ten cases treated on the Lakeside service, wounds infected with the perfringens bacilli healed rapidly. In one case, in which an infection of a stump was present in which this bacillus was found associated with other bacteria, the use of the vaccine brought subjective as well as objective improvement. The wounded patient insisted that the treatment had helped to diminish his pain. Objectively, the discharge had very evidently diminished in quantity. In a series of eight cases treated on Dr. Blake's service, in which the *Bacillus perfringens* likewise had been found, one patient in whom the vaccine treatment had been instituted rather late died. In the others, the rapid subsidence of temperature and the comparative rapidity with which the wound healed seemed an indication of its efficiency. It is needless to say that the number of cases treated is far insufficient to be able to draw definite conclusions. They *are* sufficient in number to indicate the path that might be followed with possibly excellent results.

Of vaccine and serum therapy in general we have not been given sufficient cases to draw any very definite conclusions. Antistreptococcus serum has been used in five instances. Two cases of streptococcus septicemia did not respond, although large doses of the serum were administered intravenously. One soldier whose wound discharge revealed, on examination, the presence of anaerobic streptococci, was healed in a remarkably short space of time after the use of the serum, a rapid subsidence of the temperature and a marked subjective increase of comfort following injection. In two other cases the use of the serum locally in wounds seems to have been of help. The press of work has not enabled us to follow up consistently this form of treatment.

The use of autogenous vaccines has been limited. Several cases of staphylococcus septicemia did not respond. Two local infections have been followed by amelioration of the symptoms.

May I be permitted to make a plea here for a more extended use of this method of therapy? When, if not at such a time, can we draw definite conclusions as to its value?

The most interesting form of wound infection encountered here has naturally been that of the gaseous gangrene — not a newly discovered disease, as supposed in some quarters, but a fairly old disease, which, owing to the concentration of individuals and the methods of warfare, has sprung suddenly into prominence. Infection of wounds by anaerobic bacilli had been seen in previous wars. The question as to the anaerobic nature of the infection was naturally left undetermined. Bacteriologic laboratories then, as today, were not considered a sine qua non. Small wonder that it had been left to us to combat this disease with its etiology and therapy practically unknown.

The first essential naturally was to determine definitely the actual nature of the disease. The first definite case in which the bacillus was isolated from the blood, sufficiently early after death to make its causal rôle absolute, occurred at this ambulance. A culture of the heart's blood, taken three hours after death, proved to be infected exclusively with the *Bacillus perfringens.* Since that time the number of cases has multiplied in which the *Bacillus perfringens* has been found to be the causal factor. There are other bacteria, however, that will produce gas in gangrenous tissues. The *Bacillus proteus,* the *Bacillus coli* at such a time do not remain innocent invaders. In eight undeniable clinical cases of gaseous gangrene, we have in seven instances found the perfringens; in one other instance the *Bacillus putrificus* was associated with the streptococcus. In two of these instances the use of the Weimberg vaccine, given at a late date, did not prevent the patient's death. We have not been able to infect guinea-pigs with this bacillus alone. Only by the previous injury of tissue have we been able to produce what may be clinically called gaseous gangrene. At the Pasteur Institute, injury of the muscle seems to have been all that was sufficient.

Pathologically, the lesions have been almost uniform. A punctured wound of the skin, associated in every case with injury to a large blood vessel, and in most cases with a fracture of the bone — this seems to have been a sine qua non. Following this, at intervals of from one to four days, infection with superficial gangrene, extensive destruction and necrosis of the tissues immediately adjacent to the wound, marked cloudy swelling of the muscles above and below the wound, extensive edematous infiltration interspersed with gas bubbles varying in size, are always present, and, externally, a characteristic discoloration of the skin, with a characteristic, pungent fetid odor, once smelled, never forgotten. Vesicles, varying in size from that of a pea to almost as large as the flat of the hand, are present, filled with a sanious fluid. Occasionally this fluid was found straw-colored. These blebs were examined bacteriologically; in a few instances they showed the presence of the characteristic bacillus; in other instances no bacillary infection could be found, with perhaps the exception of the banal skin bacteria. The examination of the serous infiltrating fluid showed invariably, except in the case previously mentioned, the bacillus of Welch. In some cases the characteristic changes in the tissues remained localized to the affected limb; the opposite limb, or even the opposite part of the body, showed none of these. Occasionally the local changes seemed to have been arrested at Poupart's ligament, even though the blood was later found full of bacteria. In all cases, except where the *Bacillus putrificus* was found, the heart was found to be filled with bubbles of gas, and likewise other larger vessels of the body, as well as the vessels of the brain. The hemorrhage underneath the skin layer found so often in biopsies as well as at necropsy, could be explained after a histologic examination of the tissues. The toxin of the bacillus seems to exert a special selective action on the muscular layers of the blood vessel walls, so that an escape of the blood becomes almost natural.

Despite the small number of cases examined, I feel safe in venturing to say that the production of gas plays a not unimportant rôle in the causation of death in this disease. The acute attacks of pain complained of by the patient previous to death, the rapidity with which the fatal symptoms set in, can only be likened to caisson disease, in which air emboli are the chief pathologic factor.

In cases of abscess with gas, when the septicemic features of the disease have not developed, it is the toxin production, I am sure, that is responsible for the wearing down of the patient's vitality. Histologically the changes can best be summed up as hemorrhage, edema and gas production. The parenchymatous changes in the muscle fibers which are the predominant features histologically are an early and well-marked pathologic change constantly present. This undoubtedly contributes in a large measure to the pouring forth of blood cells and the general infiltration of the tissues with serum.

In limbs fixed immediately after amputation we have found this change, namely, the splitting and coagulation necrosis of the muscle fibers of the media, which seem to point to a special selective action of the virus of the disease on the muscle coats of the blood vessel walls.

Two cases that we have had occasion to study bacteriologically here have responded, one to amputation, and the other to an intravenous injection of the serum prepared by the injection of cultures of the *Bacillus perfringens.* This also points the way to further investigation.

The etiology of this infection may perhaps be explained by the positive presence of anaerobic bacilli in the outer clothing of soldiers. We have not carried out this phase of investigation very extensively, but on several occasions we have examined the clothing of soldiers who have been brought directly from the battlefield and have found these bacilli present.

That the presence of this bacillus is not alone the factor that permits of the production of gaseous gangrene infection is proved by the comparative frequency with which it is found in ordinary wounds. The contributing cause is always, I think, an associated lesion of a blood vessel that will produce sufficient gangrenous tissue for this bacillus to thrive in ease, and by the production of protamin toxins, break down the resistance of the surrounding tissues and enable it to continue its vicious cycle unmolested. We have found this associated injury in every case examined at necropsy. The absence of leukocytes in the immediate vicinity of the infecting area, their scavenger activities when no dead tissue is present to permit of the growth of the *Bacillus perfringens,* seem to me a fairly good indication of the soundness of this hypothesis. All these are facts which only an extended investigation can either completely verify or disprove. I trust it will fall to the lot of the laboratory units that will come here in the future to settle these points definitely. As I have said before, we have merely ruffled the surface. It remains for them to dive deep into the sea of nature and bring forth the pearls of truth.

INFANT MORTALITY DUE TO LABOR*

C. S. BACON, M.D.
CHICAGO

The conservation of infant life, the prevention of infant mortality, is a subject that has been given much attention in recent years, not only in this country but also throughout the world. A strong national society has been organized to stimulate general interest in the subject, and to secure lay and professional cooperation in controlling the causes of the high mortality.

One of the important phases of this subject is an obstetric problem. Infant mortality during labor and due chiefly to labor is very high. The accidents of labor which destroy the fetus causing stillbirth, or those which injure it so that the infant dies shortly after birth are many. A study of these accidents involves a review of many obstetric problems. In such a review, we approach the most important questions of dystocia in a way that should lead to valuable suggestions for practice.

STATISTICS OF INTRAPARTUM MORTALITY

A statistical study is interesting and valuable, but unfortunately we have little data in the United States. In the mortality statistics of the United States Census Bureau, we have mortality statistics for the registration area, which embraces 65 per cent. of the population of the United States. For the rest of the country we have only the population statistics. Even in the registration area we have no record of births. Nevertheless, it may be of some value to make estimates, using the rates of birth and mortality from other countries in order to secure a more detailed picture of the subject. Even if the approximate figures be far from exact, they will lead us into no serious error. The causes of stillbirths are the same here as in Europe, and our study will show the relative importance of the different etiologic factors in intrapartum mortality. No claim is made for the scientific accuracy of the results; they are only helpful and suggestive in the study of the obstetric problem.

Let us assume the present population of the United States as about 100,000,000, that of Chicago as about one fortieth as much and that of Illinois as two and one-half times as great as that of Chicago or one sixteenth that of the United States. Then let us assume that Chicago and Illinois have about an average birth rate and mortality rate. This is true of the mortality rate of Chicago and probably reasonable for the birth rate. Of course we know very little about the mortality rate of the rest of the state, for, unfortunately, Illinois has no vital statistics law that is recognized by the Census Bureau, and therefore it is not included in the registration area.

---

* Presented before the Chicago Gynecological Society, May 21, 1915.

Let us assume that the average birth rate for the United States and for Illinois is about 24 per thousand. This would give about 2,400,000 births annually in the United States, 150,000 in Illinois, and 60,000 in Chicago.

Brothers found the number of stillbirths in New York City to be about 8 per cent. of the births. This rate is probably too high, because the figures of the number of births on which it is based are too small. In various European clinics the rate is between 4 and 7 per cent. In the German empire it is between 3 and 5 per cent. There are nearly 3,000 stillbirths reported in Chicago, or, according to our estimate about 5 per cent. of the births. The number of reported stillbirths is probably everywhere somewhat below the actual number occurring. We shall probably not be far from the truth if we say that there are 120,000 stillbirths annually in the United States, 7,500 in Illinois and 3,000 in Chicago.

In considering the question of intrapartum mortality, it is necessary to determine what proportion of fetal deaths occur before the onset of labor and how many occur during labor. This fact could be determined easily if the condition of the stillbirths was reported, for, as is well known, the fetus becomes macerated when it remains in the uterus long after death. Reports from a number of clinics show that in nearly half of the stillbirths the fetuses are macerated. It is also important to observe that the proportion of macerated fetuses is much greater among the premature than among the children at or near term. These premature, nonviable and macerated fetuses represent the stillbirths due to antepartum disease of the mother or fetus, such as syphilis, nephritis, infection, etc. A study of this group is important, but not within the scope of this paper, which is concerned only with intrapartum mortality. Accepting the fact that, without great error, from two fifths to one half of the fetal deaths occur before labor, we may take from one half to three fifths of the figures given before for the number of nonmacerated or recently dead stillbirths, that is, for the fetal mortality during labor. We then have from 60,000 to 70,000 for the United States, about 4,000 for Illinois and 1,600 for Chicago.

In studying the effect of labor on infant mortality, we must consider not only the number of stillbirths, but also the number of deaths that result from accidents of labor when death occurs within a few days of birth. The census report gives over 5,000 deaths from "injuries of labor" in the registration area. This would correspond to about 8,000 from the whole United States. There are also about 29,000 deaths during the first week of life from congenital debility and prematurity in the registration area, or 45,000 in the United States. Over half of these infants are under 1 day old. It is of course impossible to say for how many of these deaths the labor is responsible, that is, how many could have been prevented by a better management of labor. The premature child is more easily injured even in a spontaneous and apparently normal labor. Strong uterine contractions with a deficiency of liquor amnii may produce hemorrhage in the brain or lungs. Likewise, lack of care immediately after birth will cause refrigeration to 94 F. or lower, which becomes the important factor in the early death of the child. It is certainly conservative to estimate that from 5,000 to 6,000 of these 45,000 deaths could be prevented by a better conduct of labor.

Moreover, there are in the registration area nearly 1,000 deaths during the first seven days from convulsions, and a like number from bronchitis, bronchopneumonia and pneumonia. This will correspond to about 1,600 deaths in the United States in each of these classes. Certainly a large number of these are due to injuries and accidents of labor, and probably nearly half are preventable. If we say that 7,000 of the 56,000 deaths in the first seven days of life not due to injuries of labor are due to labor, we are undoubtedly within the limit of conservative statements. Adding to these the 8,000 ascribed to injuries of labor, we have 15,000 children dying from labor within a week, and half of them the first day.

We then have the following figures denoting the number of deaths due to labor: For the United States, 65,000 stillbirths and 15,000 deaths subsequent to birth, or 80,000. Likewise in Illinois, 5,000, and in Chicago, 2,000. This would give a fetal mortality due to labor of 3⅓ per cent.

In the recent presidential address of J. Whitridge Williams before the American Association for the Study and Prevention of Infant Mortality, the author makes a study of 705 fetal deaths in 10,000 cases of labor. In this series were included all deaths during labor as well as those occurring during the first two weeks after birth. Selecting out the cases probably due to labor to compare with our own, I find 285, or a fetal mortality of 2.85 per cent. The causes of fetal death were as given in Table 1.

TABLE 1.—CAUSES OF FETAL DEATH

Cause	No.
Dystocia	124
Placenta praevia	22
Ablatio placentae	13
Toxemia	46
Prematurity (one eighth of the cases)	6
Unknown (not macerated)	74
Total	285

CAUSES OF INTRAPARTUM MORTALITY

We may now consider the influence of malpresentation of the fetus, other forms of dystocia and obstetric operations in determining the intrapartum mortality. Cross-presentations are almost always fatal unless corrected by operation. If the frequency is about 0.5 per cent., the number of cross-births in the United States is about 12,000 annually. An average death rate of 40 per cent. gives us a mortality of 4,800. Similar computations give us 300 deaths from cross-births in Illinois and 120 in Chicago.

Prolapse of the cord is responsible for about the same number of deaths. This accident occurs in many of the cross-births as well as in breech presentations, and is responsible for many of the deaths charged to these malpresentations.

Face and brow presentations taken together are slightly less frequent than cross-presentations, but the mortality should not average much above 12 per cent. This would give about 1,500 deaths yearly in the United States, from 90 to 100 in Illinois and 40 in Chicago.

Breech or pelvic presentations occur in about 3 per cent. of all labors. This rate would give 72,000 breech labors yearly in the United States. The total mortality is from 20 to 25 per cent., corresponding to from 15,000 to 18,000 deaths due to this condition. Likewise we find in Illinois 4,500 cases with a mortality of about 1,000, and in Chicago 1,800 cases with a mortality of 400. In these cases, prolapse of the cord also plays a rôle.

Taken together, we have about 24,000 deaths from the three varieties of malpresentation. As the total number of births in malpresentations is about 4 per cent. of the total number of births or about 100,000 annually, we have the infant mortality about 24 per cent. This leaves about 56,000 infant deaths in skull presentations, or about 2.4 per cent. In other words, the infant mortality due to labor is ten times as great in these malpresentations as in skull presentations.

Passing now to the skull presentations, I shall consider the forceps operations. It is very difficult to estimate the frequency. In some sections, forceps are applied by physicians in from 40 to 50 per cent. of all cases. In other districts the frequency of forceps does not exceed that of well-managed clinics, that is, from 2 to 4 per cent. Probably if we consider the whole country as well as the state, we shall be conservative if we estimate the frequency to be between 6 and 7 per cent. of all labors. That would give us 160,000 forceps operations in the United States yearly, 10,000 in Illinois and 4,000 in Chicago. The mortality from forceps differs greatly according to the kind of operation. Low forceps are not very dangerous, while high forceps have a fetal mortality of from 50 to 90 per cent. Probably an estimate of 15 per cent. fetal mortality for all operations is conservative. This would give us about 24,000 deaths annually in the United States, 1,500 in Illinois and 600 in Chicago.

To these sources of infant mortality we may add eclampsia, or puerperal albuminuria and convulsions, as it is called in the International List, which is the cause of about 4,000 fetal deaths each year, rupture of the uterus, placenta praevia and ablatio placentae, everyone of which caused from 1,600 to 2,000 fetal deaths annually. Also a number of other rare accidents of labor or kinds of dystocia add to the infant mortality. Many of the deaths due to these causes have been already included under some other heading. This group adds about 12,000 deaths to those already enumerated in the preceding paragraphs.

Summing up, we find Table 2 expressing the approximate infant mortality from the causes already given.

TABLE 2.—CAUSES OF INTRAPARTUM INFANT MORTALITY

Causes	In United States	In Illinois	In Chicago
Malpresentations	24,000	1,500	600
Forceps operations	24,000	1,500	600
Miscellaneous causes	12,000	750	300
Total	60,000	3,750	1,500

Recalling the estimate of 80,000 deaths due to the accidents of birth, we find 20,000, or 25 per cent., unaccounted for. It is interesting to compare this with Williams' findings. He gives 127 deaths due to unknown causes. Fifty-three of this number are macerated stillbirths, however, leaving seventy-four unknown, or 26 per cent. of the 285 deaths probably due to labor. This result probably corresponds pretty well with the experience of most obstetricians. For about every fourth child that dies during or shortly after the labor, the death cannot be attributed to any of the accidents of labor or forms of dystocia, already enumerated. For reasons about to be given, I shall ascribe these deaths to the kind of dystocia not yet considered, namely, abnormal uterine contractions.

Completing our table and reducing it to percentages, we have the data given in Table 3.

TABLE 3.—CAUSES OF INTRAPARTUM INFANT MORTALITY

	Per cent.
Malpresentation	30
Forceps operations	30
Miscellaneous causes, including placenta praevia, ablatio placentae, ruptured uterus, toxemia, etc.	15
Pathologic uterine contractions	25

PATHOLOGIC UTERINE CONTRACTIONS

I wish to call special attention to the last cause and try to justify ascribing so much importance to it. The danger of abnormal uterine contractions is not, as a rule, sufficiently recognized. Before labor begins, the oxygenation of the fetal blood occurs in the placenta. A continuous and abundant circulation of the maternal blood furnishes the oxygen and removes the waste from the fetal blood. When the uterine contractions begin, the maternal circulation is disturbed. So long as the contractions last only a short time and are separated by considerable intervals of relaxation, there is no appreciable disturbance to the fetus. Our main index of the fetal condition is its circulation or heart tones. The frequency of the heart tones changes but little or not at all during the early contractions of labor.

When the contractions last longer and occur more frequently, there is more disturbance in the placental circulation and more derangement in the fetal circulation. If the contractions last more than one and one-half minutes, and if the intervals between contractions are shorter than the contractions themselves, the condition is pathologic and dangerous. If the contractions become more frequent and prolonged so that there is hardly any interval, we have the condition called tetany uteri, which almost always results in fetal death.

Such excessive contractions may occur early in labor, but they generally come on later. They are often the reaction of the uterus to obstacles to delivery, and so occur in contracted pelves, bad presentations, etc. They are excited by operative interference. They are the cause of fetal death not only in the 25 per cent. of causes given in the table, but also in some of the other categories. In all malpositions, fetal death is frequently due to excessive contractions, excited by the delay to labor. It may be true that in 50 per cent. of all intrapartum fetal deaths, the immediate cause of death is excessive uterine contractions.

If it should be objected that 20,000, or 25 per cent., of all fetal deaths is too large a number to be ascribed to this cause, it must be remembered that the mortality rate is nevertheless small. From 2,400,000 labors each year we deduct 100,000 malpositions and 200,000 forceps cases and cases of toxemia, placenta praevia, etc., leaving 2,100,000, in which 20,000 deaths make less than 1 per cent. A certain number of these cases are undoubtedly contracted pelves, and the injuries produced by the pressure required to mold the head to make its translation possible are factors that combine with the excessive uterine contractions to injure the child. It is, indeed, difficult always to apportion the blame. Even when postmortem examinations are made, the findings are not decisive. A careful study of the clinical history is, however, often conclusive. The contractions are normal for hours, and the child in good condition. Then comes a period of perhaps only an hour or two of very severe pains, long and hard, with short intervals, after which the fetal heart tones are wanting.

It is very important, therefore, to watch the uterine contractions with great care in long and hard labors, and especially toward the end of labor, when excessive contractions are more apt to occur. The diagnosis of the contractions is easily made by watching the patient and noting the hardening of the uterus by laying the hand on the abdomen. The diagnosis of the condition of the fetus is made by counting the fetal heart tones. Whenever there is danger, the heart tones should be counted every ten to twenty minutes.

The management of excessive contractions to prevent fetal death is to control the contractions. The best means is the hypodermic injection of morphin, and anesthesia. One-fourth grain of morphin is generally sufficient in the first stage of labor. If necessary, this dose could be repeated, for at this time there is not very much danger of morphin affecting the child. In the second stage, ether may well be combined with morphin, or substituted for it. Should the obstacle to delivery that excites the excessive uterine contractions be at the obstetric outlet, that is, should the head be on the perineum and held back by a tense, unyielding vulvar ring, episiotomy should be done. If the head is not at the vulva but down in the pelvis, and the cervix is well dilated, and if, in spite of morphin and anesthesia, the danger to the child is great, forceps may be applied. As a rule, however, forceps will increase the danger of fetal asphyxiation and should not be used unless an easy and quick extraction is possible.

MORTALITY FROM THE USE OF FORCEPS

The prevention of intrapartum death in case of bad presentation involves the correct management of these forms of dystocia, and cannot be entered on in detail in this paper. In regard to the deaths due to forceps operations, it must be said that forceps are employed much too frequently—often on account of the entreaties of the patient and her friends, often to hasten the labor for the convenience of the physician. Whenever forceps are used for these reasons, and the child is lost, its death is rightly charged against the operation, which is not far removed from the category of malpractice.

There is a great difference in the danger of high forceps and low forceps. The former has been used far too much in contracted pelves. We have learned that other operations are safer both to mother and to child. Cesarean section or hebosteotomy is in proper cases to be chosen, while the induction of premature labor must be considered in cases seen early enough in pregnancy. Above all, these cases should be studied long and with care. Exact diagnosis, not only of presentation and position, but also of station, should be made. One who rushes into a high forceps operation thinking he has to do with a head in the pelvis, and then is astounded to find that he must exert all his strength to extract a child that is dead or dying, should learn that obstetrics has advanced in recent years, and that the high forceps is an operation that is very nearly discredited.

2156 Sedgwick Street.

THE LATER HISTORY OF THE TYPHOID CARRIER H. O.

WILBUR A. SAWYER, M.D.
Director of the Hygienic Laboratory of the California State Board of Health
BERKELEY, CALIF.

In two previous articles, the history[1] of a typhoid carrier, H. O., and his treatment by typhoid vaccine[2] have been reported. The more recent developments in his case show that he was not cured by the vaccination or by the extirpation of the gallbladder, and that after an interval of many months, during which typhoid bacilli could not be found in the feces, he infected other persons.

Through the courtesy of Surgeon R. M. Woodward, medical officer in command of the United States Marine Hospital in San Francisco, I have had the privilege of drawing on the records of the hospital for the greater part of the material here presented.

REVIEW OF THE EARLIER REPORTS

The sailor, H. O., was sick with typhoid fever in the United States Marine Hospital in San Francisco from Nov. 15, 1907, to Jan. 15, 1908. During a period of four years, from March 6, 1908, to March 19, 1912, he worked on several steamships, but most of the time on the *Acme*. During this period he infected twenty-seven officers and sailors with typhoid fever. Four of them died. An investigation by the San Francisco Department of Health into the cases on the *Acme* brought H. O. under suspicion as a carrier and the source of the infection. He was studied in the City and County Hospital for a period of two weeks in December, 1911, but typhoid bacilli were not found by the city bacteriologist in a series of examinations of his feces, undoubtedly owing to intermittence in the discharge of the bacilli in detectable numbers.

The State Board of Health later gathered circumstantial evidence which pointed to H. O. as a carrier responsible for the cases, and a specimen of feces obtained March 3, 1912, was found to contain many typhoid bacilli.[1] H. O. did not handle or serve food on shipboard, and it is probable that the infection was transmitted to his comrades in various ways, but chiefly through the water in a cask from which the men dipped drinking water.

March 19, 1912, Surgeon James M. Gassaway offered to admit H. O. to the United States Marine Hospital. Since that time, except for a short period of parole, H. O. has remained voluntarily at the hospital, although technically under quarantine by the California State Board of Health. Every effort has been made by the staff of the hospital to free him from the carrier state.

The article by Currie and McKeon[2] takes up the history at this point. Between March 28 and Oct. 14, 1912, specimens of feces were examined weekly and biweekly at the laboratory of the United States Public Health Service in San Francisco. The typhoid bacillus was isolated twelve times, but not later than June 19. Examination of the urine consistently give negative results.

In an attempt to cure H. O., an autogenous typhoid vaccine was administered between April 27 and June

28, 1912, in ten doses increasing from 25 million to 1,500 million bacilli. As typhoid bacilli could not be found in the stools from June 19 to October 14, a period of nearly four months, it was suspected that the treatment had resulted in a cure, but Currie and McKeon held their final conclusion in reserve pending more prolonged observation.

PERSONS INFECTED DURING THE PATIENT'S PAROLE

When the long series of examinations of the feces of H. O., made at the laboratory of the United States Public Health Service, and also two examinations made Aug. 9 and 27, 1912, in the State Hygienic Laboratory, had failed to reveal typhoid bacilli, it was agreed by Surgeon Woodward, the California State Board of Health, and the Health Department of San Francisco that it would be safe to release him temporarily from quarantine. He was discharged from the hospital, Oct. 14, 1912. He signed an agreement to report to the Marine Hospital for examination once a month for six months. It was understood that this provisional release from quarantine would be made permanent at the end of that time if his condition remained satisfactory. He reported according to the agreement, and examination of his feces continued to give negative findings. He was employed from Oct. 20, 1912, to about Jan. 10, 1913, as winch driver on the steamer *Noyo* of the coastwise lumber trade.

Nov. 15, 1912, a seaman, O. H., from the *Noyo* was admitted to the United States Marine Hospital in San Francisco for typhoid fever. He recovered and left the hospital Jan. 14, 1913.

Another seaman from the *Noyo*, F. C., was admitted to the same hospital for typhoid fever, Dec. 23, 1912. He had a severe and typical attack. The Widal test was positive. He died, December 28.

Jan. 9, 1913, a sailor, L. K., ill with typhoid fever, entered the United States Marine Hospital in Los Angeles. He had been on the *Noyo* from Dec. 16 to 24, 1912, and in all probability had been infected between those dates. The diagnosis was confirmed by a positive Widal test. This patient recovered.

It seemed highly probable that these three sailors had received their infection from H. O. while working with him on the *Noyo*, a ship previously free from typhoid fever. The captain and crew of the *Noyo*, knowing about the experience on the *Acme*, suspected that this was the case. As a result H. O. was discharged about Jan. 10, 1913, and the seamen's union asked the Marine Hospital to make an investigation.

The investigation was made by Passed Assistant Surgeons D. H. Currie and H. G. Ebert of the United States Public Health Service. It showed that the conditions on the *Noyo* were favorable for the transference of typhoid fever from a carrier among the crew to the other sailors. The men secured their drinking water from a dilapidated water tank having a common drinking cup tied to it. In using the cup the hand was partially immersed, and pollution of the water in the tank was inevitable. Moreover, this tank was situated near the water-closet, which was in an unclean condition at the time of the inspection. The investigators suspected that H. O. was the source of the infection and recommended that he be again placed in quarantine at the Marine Hospital, and that the nature of the water containers used on coastwise vessels entering the port of San Francisco be called to the attention of the State Board of Health. The investigators expressed the opinion that a tight container for drinking water with a faucet would greatly lessen the chances of infection if a carrier were aboard, and that the arrangement exemplified on the *Noyo* was a constant menace to sailors. The conditions for transfer of infection on the *Noyo* were very similar to those found earlier on the *Acme*.[1] The open water-cask of the latter vessel had furnished an obvious opportunity for the transfer of infection.

The series of typhoid cases on the *Noyo* stopped when H. O. was discharged, just as the long series on the *Acme* had abruptly terminated when he left that ship.

Jan. 17, 1913, H. O. was readmitted to the United States Marine Hospital in San Francisco, and was again placed under quarantine by the State Board of Health. During the three months of his parole he had infected three persons, one of whom had died.

REMOVAL OF GALLBLADDER

Examination of the feces of H. O., Dec. 27, 1912, and Jan. 23 and Feb. 6, 1913, failed to reveal the typhoid bacillus, but it was present in a specimen obtained January 28. This positive specimen proved that the patient was still a typhoid carrier, a conclusion already reached on account of the infections on the *Noyo*.

At that time the existing literature gave considerable assurance that chronic carriers discharging typhoid bacilli in their feces usually owed their condition to a diseased gallbladder, and that its extirpation would result in a cure. After mature consideration Surgeon Woodward recommended removal of the gallbladder, and H. O., anxious to be freed from the danger of harming others, consented to be operated on. Feb. 12, 1913, Surgeon Woodward operated on H. O. and removed the gallbladder and its duct. H. O. rapidly regained his usual good health.

The gallbladder, contrary to expectations, contained no gallstones and was normal. A painstaking bacteriologic examination at the laboratory of the United States Public Health Service in San Francisco showed that the contents of the gallbladder did not contain typhoid bacilli, although colon bacilli and a few other organisms were present. In this carrier the gallbladder was not the focus at which the intermittent infection of the intestinal contents originated. It may, nevertheless, have been a place favorable to the multiplication of typhoid bacilli received in the bile from a focus in the liver, if such a focus existed.

After the operation, frequent examinations of the feces of H. O. were made. Nine examinations from March 4 to April 1 were negative. April 8, 1913, a specimen was obtained from which the typhoid bacillus was isolated. The removal of the gallbladder, like the treatment with typhoid vaccine, had failed to cure the carrier state. In necropsies it has been shown a number of times that the gallbladder of a typhoid carrier may be free from typhoid bacilli. Bindseil,[3] Messerschmidt[4] and Goebel[5] have reviewed the literature and have presented cases of their own. In five out of twenty-two thorough necropsies on chronic typhoid carriers, the typhoid bacillus was not present in the gallbladder. In the series of twenty-two cases, the typhoid bacillus was not infrequently found in the gallbladder and in the bile ducts of the liver, usually in the contents, and sometimes in the walls. In rare instances it was found in the spleen, and in single instances in the bone marrow, lung, and (in the presence of tuberculous lesions) in the suprarenal and kidney.

LATER EXAMINATIONS

From April 10, 1913, to April 7, 1915, a period of two years, the feces of H. O. were examined seventy-one times and typhoid bacilli were found in only three specimens, obtained Nov. 28 and Dec. 5, 1913, and Feb. 11, 1914. During the last fourteen months of this period, forty-two examinations were made and all gave negative results. In the examinations a suspension of the feces in broth or sterile water was streaked over the surface of Endo or Drigalski medium, or both. After proper incubation the typhoid-like colonies were studied further by cultural and serologic methods.

ISOLATION OF THE TYPHOID BACILLUS FROM THE STOMACH CONTENTS

When the examinations of feces had given negative results for over a year, Assistant Surgeon N. E. Wayson, medical officer in charge of the laboratory of the United States Public Health Service in San Francisco, used a method suggested by Carnot and Weill-Hallé.[6] On two occasions he obtained bile for examination by feeding H. O. 150 c.c. of olive oil on an empty stomach and removing the stomach contents one hour later through a stomach tube. After allowing the stomach contents to stand, he removed and examined the lower layer, containing the bile. In the first specimen, obtained Jan. 26, 1915, typhoid bacilli were not found, but an organism was isolated which resembled the paratyphoid A bacillus. From a second specimen, obtained in the same way, March 16, 1915, the typhoid bacillus was isolated. An examination of the feces eight days earlier had been negative. The finding of typhoid bacilli in stomach contents containing bile showed that H. O. was still a carrier, March 16, 1915, and suggests that the bacilli may have come with the bile from the liver.

ISOLATION OF THE TYPHOID BACILLUS FROM FECES OBTAINED BY PURGATION

April 12, 1915, H. O. was given podophyllum in the evening. The following morning magnesium sulphate was administered. During the next twenty-four hours three stools were obtained. The first was firm, like most of the stools from H. O., and the second was soft. Typhoid bacilli could not be found in these two specimens. The third stool was semi-fluid, and Dr. Wayson found that it contained typhoid bacilli in large numbers. During the preceding fourteen months, typhoid bacilli had not been found in the feces of H. O.

When H. O. was being investigated by the State Hygienic Laboratory in March, 1912, a semifluid stool containing very many typhoid bacilli was obtained after the administration of fluidextract of cascara and magnesium sulphate.[1] It was suspected that active peristalsis increased the number of typhoid bacilli in the feces by stimulating the flow of infected bile (or other material), or possibly by enabling more of the typhoid bacilli to survive some unfavorable condition in the intestinal contents.

VIRULENCE OF THE TYPHOID BACILLUS FROM H. O.

That the typhoid bacilli from H. O. were highly virulent had been repeatedly shown by severe and fatal cases among the sailors who came in contact with him. Additional evidence was obtained through an accident in the State Hygienic Laboratory.[7] June 15, 1914, an assistant engaged in making an antityphoid vaccine attempted to transfer with a pipet a suspension of live typhoid bacilli of the strain originally obtained from the feces of H. O., March 3, 1912. A small amount of the suspension was drawn against the tip of the tongue and the teeth. The mouth was at once washed out repeatedly with 50 per cent. alcohol. Nine days later the symptoms of typhoid fever began with headache. The course of the disease was mild and brief. The temperature did not go above 39.6 C. (103.2 F.) and returned to normal on the ninth day of the illness. The Widal test was negative at the onset, but strongly positive later. This accident showed not only that the typhoid culture isolated from H. O. was virulent, but also that a culture which had been grown on nutrient agar for two and a quarter years and transferred at least monthly was still capable of producing typhoid fever in human beings.

SUMMARY AND CONCLUSIONS

1. Although frequent examinations of the feces of the typhoid carrier H. O. gave negative results for four months after he had been treated with autogenous typhoid vaccine, he infected three persons when subsequently released from quarantine on parole. The total number of persons infected by this carrier is thirty, including five who died.
2. In a further attempt to cure this carrier, the gallbladder and its duct were removed surgically, but the typhoid bacillus was found in the feces several times after the operation. Examination of the gallbladder showed that it was normal and that its contents were free from typhoid bacilli.
3. After forty-one successive examinations of feces during a period of fourteen months, all with negative results, the typhoid bacillus was isolated from stomach contents containing bile.
4. Certain typhoid carriers are unusually dangerous and must be controlled by quarantine or other adequate supervision.

Health Leaflets.—The Bureau of Public Health Education of New York City, in cooperation with neighborhood societies, publishes and distributes monthly neighborhood chronicles in the form of a four-page health leaflet, containing on the first page local news of the paricular district of the city from which the leaflet will be distributed. They will be issued from about ten different sections of the city. The remainder of the matter in the leaflet will be the same in each. The remainder of the matter in the leaflet will be the same in each. This is expected to be an effective means of reaching the public in regard to health matters which affect them most closely. The leaflets will be distributed from house to house by the neighborhood associations.

RECOVERY IN TWO CASES OF STREPTOCOCCUS MENINGITIS FOLLOWING LUMBAR LAMINECTOMY AND DRAINAGE

WILLIAM E. LEIGHTON, A.B., M.D.
Fellow of the American College of Surgeons; Assistant Professor of Surgery, St. Louis University School of Medicine; Visiting Surgeon, St. Louis City Hospital; Associate Surgeon, Barnard Free Skin and Cancer Hospital

AND

J. A. PRINGLE, M.D.
Chief Resident Physician and Resident Alienist, St. Louis City Hospital

ST. LOUIS

The mortality of streptococcus meningitis is so very high that any method of treatment which offers even a slight possibility of a cure of this condition is deserving of our consideration. While the treatment which we have employed is not a new one, it has proved so successful and so rapidly ameliorative that we believe it should be given a more extended trial.

In 1914, Barth[1] reported recovery in three cases of streptococcus meningitis following lumbar laminectomy and drainage. It was our good fortune shortly after this to have admitted to the surgical ward of the St. Louis City Hospital the following cases:

Case 1.—*History.*—L. B., an Italian laborer, aged 65, was brought to the City Hospital, Oct. 27, 1914, at 12:50 p. m., complaining of pain in the back of his neck, vomiting for the last three days, and pains in his legs. He was very stupid and spoke little English. Questioning elicited the following indefinite history: About three weeks before he entered the hospital, he fell about 7 feet from a huckster's wagon, alighting on his head, neck and shoulders. He suffered a laceration of the scalp, and was unconscious for a few moments. Following this accident, he was unable to work because of pain in his head, weakness, nausea, and "whistling in his ears." He remained at his employer's for three weeks under home treatment, until the present attack began, at which time he was brought to the City Hospital. He was a wandering Italian laborer, and unfamiliar with the country. He was injured in a rural district, some miles from the city, and long distance telephone communication with his employer failed to add anything to the foregoing history.

Examination.—The patient was fairly well nourished and developed, and was conscious, but dazed. General physical examination revealed nothing, except those changes due to oncoming senility. Neurologic examination: Pupils small, left smaller than the right, regular in outline, react to light and accommodation; facial contraction apparently equal, tongue deviates slightly to the right; neck rigid; upper tendon jerks equal, but very active; abdominal and cremasteric reflexes equal, but active; knee-jerks equal, but very rapid; Achilles active and equal; no ankle clonus, no Babinski, Chaddock's external malleolar sign positive on the right; double Kernig; lower extremities hypersensitive; patient disoriented as to time and person, and speech is rambling if attention is not held. Temperature 97.6, pulse 72.

At 8:30 p. m. or seven hours later, the patient was unconscious, and could not be aroused. Examination revealed a very rigid neck, abdomen retracted and hard, a double Kernig sign, and Babinski with Chaddock's external malleolar sign. Temperature 98.4, pulse 62. On lumbar puncture, a turbid fluid escaped under pressure. Examination of a centrifuged specimen showed numerous pus cells, with extracellular organisms resembling streptococci. Bouillon and agar cultures examined the following day showed pure cultures of streptococci. After lumbar puncture, the diagnosis of purulent meningitis was justified, and immediate operation advised.

Operation.—The patient was prepared for operation, and at 11 o'clock, under spinal anesthesia, a typical lumbar decompression was performed. The spinal anesthesia was a complete success. An incision was made over the third and fourth lumbar vertebrae. The muscles were separated from the spines of the third and fourth vertebrae, and when the bleeding was controlled, the spinous processes were removed at the base with bone forceps. The Hudson burr was used to perforate the laminae at the base of the divided spinous process, and the rest of the laminae were removed with rongeur forceps. The ligamentum subflavum was then incised to expose the dura of the cord. In order to prevent the too rapid escape of the spinal fluid, it was thought best to lower the head of the table. The dura was then incised and a free escape of turbid fluid took place, which was readily controlled by gauze sponges. A rubber dam was then inserted to the dura and the wound carefully closed in layers except for the drain in the lower end of the wound.

The postoperative course of this case was uneventful, except for loss of sphincter control for a period of about nine days. His temperature was never above 99 degrees; he regained consciousness after two days and complained of having headache for several days. Neck rigidity disappeared on the fifth day following operation, and Kernig's sign disappeared several days later. The drain was removed on the fifth day following operation. On the fourteenth day, the patient was up in a wheel chair, and was walking two days later. Cerebrospinal fluid escaped from the wound almost until the time of his discharge, but the wound closed externally with slight meningocele. He was discharged, recovered, Nov. 27, 1914.

Case 2.—*History.*—M. K., a schoolgirl, aged 8, was brought to the City Hospital Dec. 16, 1914, with the following history: Five weeks before, she had become ill with an attack of tonsillitis, to which she was subject. She apparently recovered from this attack, but about three weeks ago her ears began to ache, and a family physician, who was called, put drops in her ears, which gave her relief. At this time, a swelling about the size of a walnut appeared behind her right ear, but soon disappeared. December 13, the patient again became ill, complaining of severe headache, and was brought to the hospital three days later. On her entrance to the hospital, the child appeared quite ill. She was conscious and rational, but cried and moaned from pain in her head. She vomited several times the day of her entrance. General physical examination revealed no gross lesions; pupils were equal and reacted to light and accommodation; tonsils were large and injected; her neck was slightly stiff, but yielded to manipulation with some pain; she had slight tenderness over the right mastoid. Temperature 99.8, pulse 92. Neurologic examination elicited no pathologic reflexes; Kernig's sign was not present. At this time, a provisional diagnosis of mastoiditis was made.

For three days following her entrance to the hospital she rested well, with no medication. An ice bag was applied to the right mastoid region. Rather suddenly on the evening of December 19, three days after entrance, her temperature rose to 100.4, she complained of severe headache, and examination showed a rigid neck and a double Kernig. A lumbar puncture produced 20 c.c. of bloody fluid. By the next morning she had developed an internal strabismus, neck rigidity was marked, Kernig's sign was very pronounced, and her temperature was 103.4, pulse 120. A lumbar puncture resulted in 20 c.c. of cloudy fluid. Examination of a centrifuged specimen revealed many leukocytes with streptococci. Cultures examined the next day showed pure cultures of streptococci. At 6:30 p. m. an operation was advised and lumbar decompression performed.

Operation.—Under ether anesthesia a 2-inch incision was made over the third lumbar vertebra. The muscles were separated from the spines and the third and fourth spinous processes were removed with bone forceps. The Hudson burr was then used to trephine through the laminae at the base of the divided spinous process. The ligamentum subflavum was then incised and the dura exposed. At this point the head of the table was lowered to prevent the too rapid escape of the spinal fluid. The dura was then incised and a turbid fluid escaped. A rubber dam was then placed on the dura and the muscles were sutured in place and the skin closed, except at the lower angle where the drain came out.

[1] Barth: Arch. f. klin. Chir., 1914, cv; abstr., The Journal A. M. A., Oct. 24, 1914, p. 1509.

The postoperative course of this case was much more severe than in Case 1. The temperature varied from 102 to 101 F., and did not reach normal until January 4. The most striking and alarming feature was a rapid pulse, which remained 128 to 140, until January 4, when it dropped to 96. The patient complained of backache and headache for about four days following the operation. For two weeks following the operation, she was rather weak, but while her convalescence was slow and prolonged, attention must be called to the fact that symptoms of meningeal irritation were never prominent, and after the fifth day there was no evidence of meningeal irritation otherwise than a slight rigidity of the neck and a spasticity of the limbs, which remained until about January 10. After the fourteenth day, convalescence was progressive, and the patient was discharged as recovered, Feb. 6, 1915.

The result in these cases was so remarkable that we began to look up the literature on the subject, and found reference to similar operations performed by Barth,[1] Rolleston and Allingham,[2] Wynter,[3] Cushing[4] and others, although it was later on condemned by Cushing along with the operation of cerebellar decompression combined with laminectomy and through-and-through irrigation advocated by Leonhard Hill. The objection to the method of Hill as well as that of laminectomy was that the purulent exudate at the base of the skull sooner or later blocked off the escape of the cerebrospinal fluid from the foramen of Magendie, and thus defeated the purpose of the operation. That this objection is open to argument is seen by the work of Barr.[5] He trephined a patient dead from meningitis and did a lumbar puncture, leaving the cannula in place. Then he tapped the lateral ventricles and allowed a methyl blue solution to flow into the ventricles under a very low pressure, and observed the escape of the fluid from the lumbar cannula, showing that even in this patient dead from meningitis the normal channels of the cerebrospinal fluid were not blocked. Postmortem examination showed that the methyl blue fluid had found free access to the base of the brain, and the exudate was thoroughly stained by this solution. He also did the same thing in a patient on whom he had operated as a last resort, using a normal saline solution, and observed its appearance at the lumbar opening. The patient was in no ways injured by the procedure, although dying shortly after this. On the death of the patient he repeated the same thing with the methyl blue solution, and demonstrated the patency of the normal channels. Several patients have been cured by repeated lumbar punctures,[6] and Gorse[7] reports a case of recovery of a patient on whom he had performed a lumbar puncture with a Rosenthal needle, which leaves the sheath or cannula in place for permanent drainage. The patient recovered after thirteen days of continuous lumbar drainage.

Murphy[8] described an operation of drainage of the sacral cisterna with cerebellar decompression and irrigation, and reports a recovery.

Haynes[9] and Kopetsky[10] strongly favor cerebellar decompression and drainage of the cisterna magna, but reported no cures in six cases in which operation was performed in this manner. Day[11] did not get a cure in nine cases with operation by the Haynes method. In spite of strong appeals for the operation, therefore, it does not seem to fulfil the expectations of its advocate.

The successful outcome in our cases was undoubtedly due to the early diagnosis and prompt treatment, and herein may lie the secret of success in this disease. The mortality in acute purulent meningitis is very high, and unless treated surgically is almost invariably fatal. As a rule the onset of the disease is sudden. The symptoms are intense and the course is short, rapidly tending toward a fatal issue. Netter,[12] in a study of sixty-five cases, found that fifty-four died within four days. Death is the result of two factors, increased intracranial tension and toxemia. The first factor can be influenced by repeated lumbar punctures, or by permanent drainage. The second factor of toxemia may be overcome possibly by the dilution of the toxins through the rapid secretion of the cerebrospinal fluid. It is estimated that the normal secretion is replaced every three or four hours by an entirely new supply, and in abnormal conditions, as fracture or lumbar puncture, the alteration in normal tension may result in a very rapid increase in the amount of this secretion.[13]

Streptococcus meningitis is a surgical disease, just as acute purulent peritonitis is a surgical one, and here again we see the analogy; the mortality is extremely high in peritonitis unless we early establish thorough drainage. Therefore we may perhaps draw the conclusion that early operation and permanent drainage will offer a lessened mortality in acute purulent meningitis.

VISIBLE ACUTE DILATATION OF THE STOMACH DURING LAPAROTOMY

REPORT OF TWO CASES WITH OBSERVATIONS

W. H. LUCKETT, B.S.A., M.D.
Fellow of the American College of Surgeons
NEW YORK

Frequent reports of postoperative dilatation of the stomach are made, but rarely of a case occurring which is visible through the laparotomy wound during operation. The explanations of the postoperative cases are almost as numerous as the number of cases reported. It has been said that probably more than one cause or a combination of causes may be responsible for such a condition.

I have long been of the opinion that none of the reasons heretofore named as the cause of dilatation of the stomach were entirely satisfactory. I have had the idea that in nearly all if not every case the air had been taken in through the mouth in some modified process of deglutition.

As a boy I can well remember an old horse named Charlie which, when approached for the purpose of being saddled, would gulp down large chunks of air (aerophagy), causing such distention of his belly that it was with difficulty that the girth could be properly cinched. Veterinarians are familiar with this fact relative to horses.

The two cases reported here with observations may possibly throw some light on this condition.

Case 1.—A. G., woman, white, aged 22 years, admitted to the Harlem Hospital, Monday, Sept. 29, 1913, had a negative family history, and the previous history was negative except for two attacks of appendicitis. On the preceding Friday the patient was seized with general abdominal pains which after twenty-four hours localized on the right side, in the lower quadrant of the abdomen. The patient had been nauseated but had not vomited; had had fever, and bowels had been constipated. She was brought to the hospital in an ambulance.

Examination.—The patient was fairly well nourished and developed, conscious and rational. Pupils were equal and regular, reacting normally to light and accommodation. Mucous membranes were clean and moist. Tongue was slightly coated. Throat clear. Heart was normal in outline and position; sounds clear, no murmurs heard. Pulse was regular and of good force and tension, increased in rate. Lungs were clear. Breasts were full and soft, and there were no masses or tender areas. The right side of the abdomen was rather rigid, tender and tympanitic; no masses were felt; there was no shifting dulness. Liver, spleen and kidneys were *not* felt. Skin was clear. Extremities were normal. Lymph nodes were not enlarged. Reflexes, knee jerk. Sexual organs were negative. Urine was clear, amber, specific gravity 1.020, acid; after operation, specific gravity was 1.015. Albumin, glucose, casts, leukocytes negative; few epithelia.

BLOOD EXAMINATIONS

	Sept. 29, 1913	Sept. 30, 1913	Oct. 1, 1913
No. cells counted......	100	100	100
Leukocytes	10,000	9,400	10,400
Polymorphonuclears	70%	67%	64%
Lymphocytes	30	30	30
Transitionals	1	3	6

Temperature was 102, pulse 80, respiration 20 on admission. Widal partial agglutination but no complete loss of motility. Dil. 1:40, time thirty minutes.

Operation.—Oct. 1, 1913. Nitrous oxid and ether anesthesia, Bennett and open, nitrous oxid gas two bags, ether 3 ounces, was begun at 2:55 p. m., and stopped at thirty minutes. Total time of operation was twenty minutes. Anesthesia was maintained for twenty-five minutes. Anesthesia before operation, ten minutes. Patient took anesthesia well. Skin was prepared by painting with iodin, 3.5 per cent., as usual. A right rectus incision 3 inches long was made through the abdominal wall into the peritoneal cavity. A cecum mobile was found, and an appendix that showed only slightly external inflammatory changes; tubes and ovaries were normal. The appendix was clamped, mesentery ligated, then removed. At this point patient began to swallow (?) air, and the stomach became markedly distended and presented itself at the laparotomy opening, extending well beyond the lower angle of the incision until the lower border of the stomach had reached the brim of the true pelvis. The stomach did not look pale with thin walls, as one would naturally expect from such distention, but it was solidlike, and looked more like a solid mass as a fibroid of the uterus with its red congested color and distended engorged vessels. The finger could hardly indent the wall of the distended stomach. The hand could not possibly be introduced through the wound into the abdominal cavity. It was absolutely blocked by the distended stomach. A stomach pump was hastily inserted with the greatest ease, meeting no obstruction at the cardia. The distal end of the pump was submerged in water. An enormous volume of gas was expelled, as evidenced by large bubbles that appeared in the water. The stomach began to empty and immediately returned to the normal. The abdominal wound was closed with No. 2 plain catgut in three layers, and the usual sterile dressing applied. At the time I was most impressed by the absence of epigastric protrusion or other evidences of abdominal distention. The patient made an uneventful recovery.

Pathologic Report.—The specimen is an appendix 2 inches long, white, no adhesions, no perforations, vessels slightly injected. Histologically, sections show muscularis and peritoneal coats normal, mucosa slightly thickened and infiltrated, small follicular ulcers present on mucosa.

Diagnosis.—Acute catarrhal appendicitis.

Retrospective History (by Dr. Reilly).—For the past three years the patient has been troubled with constipation. For the past year she has been complaining of other digestive disturbances about once a week; she would have attacks of sharp pain in the epigastrium, going through to back; by lying flat on her abdomen the pain would disappear gradually. It was relieved mostly by belching; the patient never vomited. There were no diarrhea, no acid eructations, no heartburn. Dizziness had been almost constant since June last. This dizziness was so marked the last few weeks that the patient had to rest after dinner each day in order to obtain relief. She says she ran a race last spring while at a picnic; at the finish she was seized with sharp pains in the right iliac region. The pain lasted about a week.

Case 2.—H. P., white man, aged 29 years, admitted to the Harlem Hospital Jan. 9, 1914, with unobtainable previous history, had been very constipated for a year and had had epigastric distress and pains. Pains came on usually from one to three hours after meals. It was impossible to get details of good history. He complained of gas and belching. For the last two weeks the pains had been very bad and he had been obliged to stop work and stay in bed. On several occasions, but especially in the last two weeks, he would wake up with his mouth full of what he thought was blood, which was dark in color. He had no cough, no shortness of breath, had never vomited, and had never seen blood in stool, but it had been very dark on several occasions. There had been no urinary disturbances.

Operation (for gastro-enterostomy).—Anesthesia, gas and ether, Bennett and open, two bags of gas, ether 5 ounces, was begun at 2:25 p. m.; operation, forty minutes; anesthesia, one hour; anesthesia before operation, ten minutes.

While the stomach, which had been pulled partly through the laparotomy wound, was being examined, it suddenly commenced to enlarge. We could distinctly feel and hear large gulps of air (?) entering the stomach and hear a noise in the throat; yet the patient was apparently not swallowing; that is, the thyroid cartilage was apparently still and there was no visible motion of the throat. The stomach was getting larger and larger and so tense that for a moment we were concerned with fear that it should rupture. Firm pressure was being made on the stomach, and an attempt was also made to replace that portion of the stomach outside within the abdomen; but it could not be done. A stomach pump was inserted with the outer end submerged in a basin of water, and large volumes of gas escaped, making itself manifest by bubbling up in the water. The stomach immediately returned to normal size and we proceeded with the examination. A healed-over gastric ulcer was found near the pylorus. A posterior no-loop gastro-enterostomy was performed. The patient made an uneventful recovery, and did not have any further dilatation of the stomach.

Retrospective History (by Dr. Reilly).—Complaint dated back two years. Pain comes on as usual immediately after meals and lasts from fifteen to twenty minutes. Patient has lost 7 pounds during the last year. Has bitter taste in mouth in the morning. Immediately after bowels move, he has severe pain in epigastric region above umbilicus often accompanied by sour eructations. The pain after meals often radiates to the back like a needle sticking him. Urine negative, sputum negative.

Blood Count.—Cells counted, 100; leukocytes, 9,000; erythrocytes, 5,200,000; polymorphonuclears, 72 per cent.; lymphocytes, 20 per cent.; hemoglobin (Sahli) 97 per cent.

It is interesting to note that there was wide divergence in opinion of all those present at both operations as to whether or not the patients swallowed. While we all agreed that we heard the noise in the throat in both cases, it was variously described. We mostly agreed that it was not an ordinary deglutition act. I believe that it was a reflex deglutition act—a kind of clonus of the muscles of deglutition so rapid as almost to escape detection, a spasmodic deglutition of air (aerophagy).

Common to the two cases was the very rapid noise in the throat, and no discoloration of the water in which the tube was submerged. It was a colorless gas that escaped. The stomach was absolutely empty; no fluid, no solid particles escaped through the tube in either case. Neither patient vomited or had abdominal distention after the operation. Neither of the patients had swallowed the anesthetic at the beginning of the anesthesia.

In Case 2, while the stomach was being held in our hands, it felt as if one was holding a gas bag while it was being filled intermittently with volumes of gas. Not only could we hear the noise in the throat and the rush of air into the stomach, but it could also be distinctly felt.

After my experience with the first case I determined to do certain things with the next case should I ever be so fortunate as to observe again such a condition. For instance, I had determined to collect the gas in a bell jar under water in order to ascertain if we had a sudden rapid elimination of gas into the stomach from some very complicated source of which at present we know little or nothing; but when the second case presented itself it came so suddenly and took us so by surprise that we were so much concerned not to let the stomach rupture that we neglected to do those things. It must be understood as a matter of course that the stomach always contains a certain quantity of gas, derived partly from gases swallowed with the saliva, partly from gases which pass backward from the duodenum. The saliva contains much more carbon dioxid than an equal volume of venous blood, a part of which is set free by the acids of the stomach. The air in the stomach is constantly undergoing changes whereby its oxygen is absorbed by the blood, and for one volume of oxygen absorbed, two volumes of carbon dioxid are returned to the stomach from the blood. Hence the amount of oxygen in the stomach is small and the carbon dioxid considerable.

If this be true, then it is not necessary for the patient to swallow the entire volume of air necessary for a given distention for two reasons: First, there is some slight increase in volume from expansion due to the increase in temperature in the stomach of from 20 to 30 F. above the temperature of the air of the operating room. The coefficient denoting the increase in volume for 1 degree F. of air whose elasticity is constant equals 0.002039, and it is probably higher; for the air heavily laden with the more expansive ether fumes, however, it is a negligible increase, to be sure, as compared to the second, the possible sudden doubling of its volume through the more complex mechanism of the interchange of gases.

The fact that both cases showed clear gas from the stomach demonstrates that if the elimination of the black hematogenous highly toxic material common to some forms of sepsis and intestinal paresis comes from the mucous membrane of the acutely dilated stomach, then it does not escape until the distention has been maintained for a definite period. About this time I commenced to watch carefully after operation my patients who were having gastric dilatation, and they were frequently observed, particularly the nervous, high strung sensitive ones, wetting their lips with the tongue, then rolling up a combined bolus of air and saliva, and frequently swallowing. One little fellow in particular who had been operated on for abscess appendicitis with considerable peritonitis had to have his stomach washed two and three times a day because of the gastric dilatation and black vomit. He did not need another washing after being cautioned to cease swallowing. I now regularly instruct patients of this type that they must not swallow air.

Although Braun and Riedel, after considerable experimental work, concluded that they found no evidences of a valvular closure of the cardia, we could not empty by forcible pressure of four hands the stomach of Case 2, but in spite of our efforts to empty the stomach, at each gulp (?) more air would enter and none leave, as if there was a valvelike action somewhere, probably at the cardia.

Considering the enormous mortality of postoperative acute gastric dilatation, variously estimated at from 63 to 75 per cent., I am impressed most by the rapid recovery of both patients without after-effects. The lesson is perfectly obvious; early emptying of the stomach before the overdistention injures the capillaries of the mucosa, and the consequent rapid filling with enormous volume of highly toxic fluids supervenes. The high mortality is due to a too late recognition of the true condition. Acute dilatation of the stomach must be maintained for some time before it can be observed as a distention of the abdomen.

18 West Eighty-Seventh Street.

THE PROGNOSIS OF AURICULAR FIBRILLATION *

HAROLD E. B. PARDEE, M.D.
First Assistant Physician Out-Patient Department New York Hospital
NEW YORK

I shall endeavor to emphasize a fact in relation to patients with auricular fibrillation which seems to me to have attracted much less attention than is due to its importance; that is, that the presence of the irregularity does not greatly increase the gravity of the prognosis.

We have a fair idea of the amount of restricted activity imposed by the different lesions of the cardiac valves, but we are only lately coming to realize that an irregular heart does not of necessity seriously cripple the individual. Sinus arrhythmia we know may be disregarded, and usually looked on as normal; extrasystoles do not seem to lead to hypertrophy or cardiac failure even when present constantly over long periods of time; but the continuous irregularity of auricular fibrillation has been considered a grave abnormality of function. My endeavor will be to point out how this impression arose, and how it should be qualified.

The inception of fibrillation sometimes comes as a distinctly sudden event in the course of the patient's history, with the prompt appearance of symptoms of

---

* Read before the Section on Internal Medicine of the New York Academy of Medicine, March 16, 1915.

considerable severity. In these cases the heart rate is rapid from the start, in the neighborhood of 120 per minute. Most frequently the rate at onset is slower than this, in the neighborhood of 80 per minute, and this rhythm may be present for a considerable time without symptoms on the part of the patient. On attempting moderate exertion, the rate increases and dyspnea, palpitation or precordial discomfort appear, though at first they do not persist for long. Without treatment, the course is one of progressively increasing limitation of activity. The dyspnea or other symptoms appear with less provocation, the heart rate is more rapid in the intervals, edema appears and the patient is confined to his room or his chair. The heart cannot maintain its efficiency with the shortened diastole resultant from the rapid ventricular rate. It tires more and more easily and is finally completely unable to carry on a sufficient circulation.

This breaking down of the cardiac reserve takes a variable amount of time, the variations depending perhaps on the quality of the cardiac muscle, on the demands the patient makes on his heart, or on the associated pathologic conditions, for fibrillation rarely occurs in an otherwise normal individual. My impression is that this period of failure varies from two or three to many months, though it is usually impossible to mark exactly the time of onset of the irregularity.

Under energetic treatment with digitalis the cardiac failure in either type of case is promptly corrected. Twenty minims of the tincture four or five times daily, or an equivalent amount of the other preparations will usually relieve the dyspnea and palpitation in 24 to 48 hours, and by the fourth day the patient is quite comfortable and the heart rate reduced to 85 or 90. By reducing the dosage of digitalis properly its toxic effects can be avoided, and the heart rate kept in the neighborhood of 60 to 80 per minute. The patient will recover his strength and be able to go about, and will be discharged. He is now, from the physiologic standpoint, just where he was at the onset of fibrillation, except that the heart has suffered from the dilatation and will the more readily increase in rate when called on for extra effort. Increased rate means shortened diastole — that is, a shortened period of rest — and in a month or more cardiac insufficiency is well reestablished.

To show what is often the course in such a case I will introduce the history of a man aged 63, with a heart moderately enlarged, and irregular, but no murmurs. He was first seen in December, 1913, having had edema of the legs at various times for four years, with varying dyspnea on exertion. After three weeks he was so well that he stopped treatment. He returned in May, 1914, again with failing heart, and stopped treatment after two weeks feeling well. He returned with cardiac failure in September and November, 1914, and in January and March, 1915, each time stopping treatment as soon as he felt well. This man is a janitor and does sweeping and cleaning only, having no heavy work.

This is the cycle which gave to auricular fibrillation its bad repute. The chronic circulatory disability with periods of marked cardiac failure, afforded a most unpleasant outlook. We are learning now how to avoid this. The patient must not be discharged when he has recovered his strength after the dilatation, but must be kept under observation, must continue the digitalis, must in fact take enough of this drug so that its effect on the vagus will maintain the heart at its optimum rate, usually about 70 per minute. In my experience this amount of digitalis has varied from 20 to 40 minims of the tincture daily in divided doses.

If by this means we maintain the heart at its optimum rate, the mere fact of irregularity seems to have little if any harmful effect on the patient's cardiac reserve under conditions of strain, and he is not subjected to those periods of circulatory failure which otherwise are a certain though irregular occurrence.

To illustrate what can be done toward making the patients comfortable and even useful and how much this gloomy prognosis must be modified, I will cite some cases under observation at present, in which the patients are able to be about and to work in spite of their irregularity, and some of them are performing unusual physical exertion. Besides the fibrillation, some of these patients have lesions which are of considerable gravity, and these lesions must be taken into account in considering the extent of the patient's disability.

REPORT OF CASES

Case 1.—A man, aged 47, weight 250 pounds, had an enlarged heart, irregular, but with no murmurs. Systolic blood pressure 240 mm. Hg, diastolic 140 mm. Hg. The urine shows a trace of albumin and at times hyaline casts. He was first seen in June, 1914, with a history of gradually increasing palpitation and dyspnea over a period of six months, and of edema for a month. Under treatment he was soon about again and complaining only of weakness in the legs; was able to climb stairs and to walk without difficulty. He has had no cardiac failure up to the present except on one occasion to be mentioned, and for two periods was at work. During September, 1914, his work involved carring 10 to 30 pounds weight up one or two flights of stairs. He would take from one to four or five loads, and then would have a period of rest. He felt so well that after three weeks he stopped the digitalis, and in ten days had to stop work on account of cardiac failure, with palpitation and dyspnea. His heart rate was now 132. He recovered under treatment, and during December he again worked, loading and delivering pianos, but had to stop this after a month owing to gradually increasing symptoms, in spite of continuing digitalis. His heart rate was 100, and he showed slight edema of the legs, and become dyspneic after walking six blocks. He was soon again in good condition, and has had since then a sedentary occupation, but must take 10 minims of the tincture twice daily to maintain his comfort, and his heart rate at 85. There have been three months of cardiac insufficiency during the last ten months; part of this was due to stopping treatment.

Case 2.—A man, aged 61, with mitral stenosis and auricular fibrillation, was first seen in August, 1914, with a history of dyspnea on exertion, of varying severity for a period of three years. For two weeks he had had marked palpitation, dyspnea on walking and severe precordial pain. There was no edema. The heart rate was 145 per minute. This man is a janitor, and besides considerable sweeping and brass polishing has to keep a large coal furnace going. After a month, by September, 1914, he was able to work and has continued to do so, taking 10 minims of the tincture three times daily. His heart rate is about 70 per minute. During December he was called on to shovel coal into the cellar. He could not do this for more than half an hour without palpitation and dyspnea. This is the only occasion on which he has complained of cardiac symptoms during his eight months under treatment.

Case 3.—A woman, aged 64, has mitral regurgitation, roughened aortic cusps and a somewhat enlarged and irregular heart. She was first seen in March, 1912, with moderate edema, considerable dyspnea and cough. This patient does housecleaning for her family, and washing and ironing, and has not been decompensated or had cardiac symptoms since coming under treatment, a period of three years. She takes 10 minims twice daily and has a heart rate of 60 or 70 per minute.

CASE 4.—*A man, aged 25, shows an evident mitral stenosis.* In November, 1912, following a very hard basket-ball game he was attacked by precordial discomfort, and palpitation, which decreased and disappeared during a month under treatment. His pulse, though regular before, was now irregular, and has remained so. By January, 1913, he had no cardiac symptoms and medication was stopped. In June, 1913, he again had slight palpitation and dyspnea which was relieved by a month of digitalis, and since then he has been under constant observation though taking no digitalis for periods of from three to four months at a time. He is an active young man in a large printing house. He played basket ball even when fibrillation was present until advised to stop it in March, 1914, and since then has kept up regular gymnasium work. He is able to run for a quarter mile without bringing on more dyspnea than would be shown by an average normal person not in training. His heart rate is usually about 75 and he has been free from cardiac symptoms for two years.

CASE 5.—A man, aged 51, with systolic blood pressure 210 mm. Hg, diastolic 130 mm. Hg, has a heart moderately enlarged and irregular, and showing no murmurs. The urine, at times, contains albumin and hyaline casts. He was first seen in July, 1914, having had increasing dyspnea on exertion and a substernal tightness for the preceding 4 to 6 weeks. His heart rate was 120. There was no edema. He returned to work in two weeks and has continued until the present under the influence of 10 minims of the tincture three times daily, the heart rate being 80. He can climb stairs freely and his work necessitates handling though not lifting 60-pound packing crates. He has been nine months under treatment without symptoms.

CASE 6.—*A man, aged 65, with a heart considerably enlarged, irregular and showing no murmurs, was seen in* September, 1914, having had some dyspnea on exertion for a year or so, increasing lately and accompanied by edema. He did not have these symptoms after a month of treatment and has been living a normal life since then. He can take long walks and climb stairs with ease. He takes no other exercise and is not engaged in work. He takes 10 minims of the tincture three times daily or if he feels a little out of sorts every four hours. He thinks that increasing the dose makes him feel better though the heart rate is always about 80. He has been seven months under that treatment.

CASE 7.—A man, aged 53, with a moderately enlarged and irregular heart, but no murmurs, was first seen in November, 1913, having had dyspnea on exertion for four months and lately edema. He worked as elevator man and porter in a wholesale house and handled boxes weighing about 30 pounds, loading them on and off the elevator. He returned to work after a month, but on stopping digitalis in January, 1914, his symptoms returned. He was away from work only ten days and has continued since then taking 20 minims of the tincture twice daily and being free from complaints. His heart averages 75 beats per minute. He was free from symptoms for seventeen months, except for a short time when he stopped treatment.

These patients are all in excellent condition at present and have continued so as long as they have remained under treatment, a period varying from seven months to three years. They are free from cardiac symptoms under the ordinary demands of their life. Two of them, Patients 1 and 2, show inability to do work of a very severe character which most of the others have not attempted; Patient 4, on the other hand, had he a regular heart, would be considered to have a remarkable degree of cardiac reserve for one with mitral stenosis.

From the course of these patients we might be able to draw two conclusions, one as to the treatment of such cases and one as to their prognosis. The question of treatment I shall not dwell on because it is pretty generally felt by now that patients with auricular fibrillation should have continual observation and almost continual medication even though they are about and feeling well. The heart needs a sufficient period of rest between beats in order to avoid fatigue and maintain its functional integrity, and this prolongation of diastole can only be obtained by keeping the heart slowed by digitalis to about 70 beats per minute. For this purpose very small doses do not suffice; at least 10 minims of the tincture, twice daily, are usually necessary.

The question of prognosis I wish most to emphasize. It should not be so gloomy as it is at present. Here are seven patients having this irregularity. They are all comfortable, all but one at work, and some of them are performing exercise of no inconsiderable severity. They are doing this, not only in spite of their irregular heart action, but also in spite of the endocarditis, hypertension or myocarditis which is present in each respective case. Were the irregularity of such serious import as it is often considered to be we could not have patients so free from discomfort as these are for such long periods of time.

Cowan, in his recent book, states that the prognosis in this type of irregularity is always more grave than in comparable cases with sinus rhythm. "The inception of permanent auricular fibrillation is the beginning of the end, though many patients are able to lead quiet lives for a year or two." Lewis, in Osler's System of Medicine, says that fibrillation "loads an already defective muscle with an extra burden, the burden of increased ventricular rate and shortened diastole."

Mackenzie appears to feel less pessimistic as to the prognosis of the arrhythmia. "It is in all probability the extent of the divers associated pathologic conditions which determines the prognosis of auricular fibrillation." He has seen patients who in spite of treatment failed rapidly after the onset of the irregularity, but has "repeatedly seen fibrillation set in and the individual be altogether unconscious of its presence" for a time. He reports the case histories of three patients who were about and living nearly normal lives for six years after the irregularity was noticed, and one for twelve years after.

It is but comparatively recently that we have learned the necessity of continual medication in the presence of auricular fibrillation. Mackenzie, who was the first to make use of it, will be noticed as having given the least severe prognosis. I feel that we should go even further than Mackenzie and say that if the heart is kept slowed by proper treatment the prognosis of auricular fibrillation should be no more grave than that of the associated pathologic condition.

SUMMARY

The continuous irregularity of auricular fibrillation has been looked on as causing a poor prognosis. This is due to stopping treatment as soon as the patient recovers from an attack of acute cardiac failure.

By continuing the digitalis in sufficient quantity to keep the heart slowed to about 70 beats per minute, there will not be a recurrence of the cardiac failure.

Seven such cases are cited in which the patients have remained under treatment without cardiac symptoms for periods of from seven months to three years, considerable severity. In these cases the heart rate is rapid from the start, in the neighborhood of 120 per minute. Most frequently the rate at onset is slower than this, in the neighborhood of 80 per minute, and this rhythm may be present for a considerable time without symptoms on the part of the patient. On attempting moderate exertion, the rate increases and dyspnea, palpitation or precordial discomfort appear, though at first they do not persist for long. Without treatment, the course is one of progressively increasing limitation of activity. The dyspnea or other symptoms appear with less provocation, the heart rate is more rapid in the intervals, edema appears and the patient is confined to his room or his chair. The heart cannot maintain its efficiency with the shortened diastole resultant from the rapid ventricular rate. It tires more and more easily and is finally completely unable to carry on a sufficient circulation.

This breaking down of the cardiac reserve takes a variable amount of time, the variations depending perhaps on the quality of the cardiac muscle, on the demands the patient makes on his heart, or on the associated pathologic conditions, for fibrillation rarely occurs in an otherwise normal individual. My impression is that this period of failure varies from two or three to many months, though it is usually impossible to mark exactly the time of onset of the irregularity.

Under energetic treatment with digitalis the cardiac failure in either type of case is promptly corrected. Twenty minims of the tincture four or five times daily, or an equivalent amount of the other preparations will usually relieve the dyspnea and palpitation in 24 to 48 hours, and by the fourth day the patient is quite comfortable and the heart rate reduced to 85 or 90. By reducing the dosage of digitalis properly its toxic effects can be avoided, and the heart rate kept in the neighborhood of 60 to 80 per minute. The patient will recover his strength and be able to go about, and will be discharged. He is now, from the physiologic standpoint, just where he was at the onset of fibrillation, except that the heart has suffered from the dilatation and will the more readily increase in rate when called on for extra effort. Increased rate means shortened diastole — that is, a shortened period of rest — and in a month or more cardiac insufficiency is well reestablished.

To show what is often the course in such a case I will introduce the history of a man aged 63, with a heart moderately enlarged, and irregular, but no murmurs. He was first seen in December, 1913, having had edema of the legs at various times for four years, with varying dyspnea on exertion. After three weeks he was so well that he stopped treatment. He returned in May, 1914, again with failing heart, and stopped treatment after two weeks feeling well. He returned with cardiac failure in September and November, 1914, and in January and March, 1915, each time stopping treatment as soon as he felt well. This man is a janitor and does sweeping and cleaning only, having no heavy work.

This is the cycle which gave to auricular fibrillation its bad repute. The chronic circulatory disability with periods of marked cardiac failure, afforded a most unpleasant outlook. We are learning now how to avoid this. The patient must not be discharged when he has recovered his strength after the dilatation, but must be kept under observation, must continue the digitalis, must in fact take enough of this drug so that its effect on the vagus will maintain the heart at its optimum rate, usually about 70 per minute. In my experience this amount of digitalis has varied from 20 to 40 minims of the tincture daily in divided doses.

If by this means we maintain the heart at its optimum rate, the mere fact of irregularity seems to have little if any harmful effect on the patient's cardiac reserve under conditions of strain, and he is not subjected to those periods of circulatory failure which otherwise are a certain though irregular occurrence.

To illustrate what can be done toward making the patients comfortable and even useful and how much this gloomy prognosis must be modified, I will cite some cases under observation at present, in which the patients are able to be about and to work in spite of their irregularity, and some of them are performing unusual physical exertion. Besides the fibrillation, some of these patients have lesions which are of considerable gravity, and these lesions must be taken into account in considering the extent of the patient's disability.

REPORT OF CASES

Case 1.—A man, aged 47, weight 250 pounds, had an enlarged heart, irregular, but with no murmurs. Systolic blood pressure 240 mm. Hg, diastolic 140 mm. Hg. The urine shows a trace of albumin and at times hyaline casts. He was first seen in June, 1914, with a history of gradually increasing palpitation and dyspnea over a period of six months, and of edema for a month. Under treatment he was soon about again and complaining only of weakness in the legs; was able to climb stairs and to walk without difficulty. He has had no cardiac failure up to the present except on one occasion to be mentioned, and for two periods was at work. During September, 1914, his work involved carring 10 to 30 pounds weight up one or two flights of stairs. He would take from one to four or five loads, and then would have a period of rest. He felt so well that after three weeks he stopped the digitalis, and in ten days had to stop work on account of cardiac failure, with palpitation and dyspnea. His heart rate was now 132. He recovered under treatment, and during December he again worked, loading and delivering pianos, but had to stop this after a month owing to gradually increasing symptoms, in spite of continuing digitalis. His heart rate was 100, and he showed slight edema of the legs, and become dyspneic after walking six blocks. He was soon again in good condition, and has had since then a sedentary occupation, but must take 10 minims of the tincture twice daily to maintain his comfort, and his heart rate at 85. There have been three months of cardiac insufficiency during the last ten months; part of this was due to stopping treatment.

Case 2.—A man, aged 61, with mitral stenosis and auricular fibrillation, was first seen in August, 1914, with a history of dyspnea on exertion, of varying severity for a period of three years. For two weeks he had had marked palpitation, dyspnea on walking and severe precordial pain. There was no edema. The heart rate was 145 per minute. This man is a janitor, and besides considerable sweeping and brass polishing has to keep a large coal furnace going. After a month, by September, 1914, he was able to work and has continued to do so, taking 10 minims of the tincture three times daily. His heart rate is about 70 per minute. During December he was called on to shovel coal into the cellar. He could not do this for more than half an hour without palpitation and dyspnea. This is the only occasion on which he has complained of cardiac symptoms during his eight months under treatment.

Case 3.—A woman, aged 64, has mitral regurgitation, roughened aortic cusps and a somewhat enlarged and irregular heart. She was first seen in March, 1912, with moderate edema, considerable dyspnea and cough. This patient does housecleaning for her family, and washing and ironing, and has not been decompensated or had cardiac symptoms since coming under treatment, a period of three years. She takes 10 minims twice daily and has a heart rate of 60 or 70 per minute.

CASE 4.—A man, aged 25, shows an evident mitral stenosis. In November, 1912, following a very hard basket-ball game he was attacked by precordial discomfort, and palpitation, which decreased and disappeared during a month under treatment. His pulse, though regular before, was now irregular, and has remained so. By January, 1913, he had no cardiac symptoms and medication was stopped. In June, 1913, he again had slight palpitation and dyspnea which was relieved by a month of digitalis, and since then he has been under constant observation though taking no digitalis for periods of from three to four months at a time. He is an active young man in a large printing house. He played basket ball even when fibrillation was present until advised to stop it in March, 1914, and since then has kept up regular gymnasium work. He is able to run for a quarter mile without bringing on more dyspnea than would be shown by an average normal person not in training. His heart rate is usually about 75 and he has been free from cardiac symptoms for two years.

CASE 5.—A man, aged 51, with systolic blood pressure 210 mm. Hg, diastolic 130 mm. Hg, has a heart moderately enlarged and irregular, and showing no murmurs. The urine, at times, contains albumin and hyaline casts. He was first seen in July, 1914, having had increasing dyspnea on exertion and a substernal tightness for the preceding 4 to 6 weeks. His heart rate was 120. There was no edema. He returned to work in two weeks and has continued until the present under the influence of 10 minims of the tincture three times daily, the heart rate being 80. He can climb stairs freely and his work necessitates handling though not lifting 60-pound packing crates. He has been nine months under treatment without symptoms.

CASE 6.—A man, aged 65, with a heart considerably enlarged, irregular and showing no murmurs, was seen in September, 1914, having had some dyspnea on exertion for a year or so, increasing lately and accompanied by edema. He did not have these symptoms after a month of treatment and has been living a normal life since then. He can take long walks and climb stairs with ease. He takes no other exercise and is not engaged in work. He takes 10 minims of the tincture three times daily or if he feels a little out of sorts every four hours. He thinks that increasing the dose makes him feel better though the heart rate is always about 80. He has been seven months under that treatment.

CASE 7.—A man, aged 53, with a moderately enlarged and irregular heart, but no murmurs, was first seen in November, 1913, having had dyspnea on exertion for four months and lately edema. He worked as elevator man and porter in a wholesale house and handled boxes weighing about 30 pounds, loading them on and off the elevator. He returned to work after a month, but on stopping digitalis in January, 1914, his symptoms returned. He was away from work only ten days and has continued since then taking 20 minims of the tincture twice daily and being free from complaints. His heart averages 75 beats per minute. He was free from symptoms for seventeen months, except for a short time when he stopped treatment.

These patients are all in excellent condition at present and have continued so as long as they have remained under treatment, a period varying from seven months to three years. They are free from cardiac symptoms under the ordinary demands of their life. Two of them, Patients 1 and 2, show inability to do work of a very severe character which most of the others have not attempted; Patient 4, on the other hand, had he a regular heart, would be considered to have a remarkable degree of cardiac reserve for one with mitral stenosis.

From the course of these patients we might be able to draw two conclusions, one as to the treatment of such cases and one as to their prognosis. The question of treatment I shall not dwell on because it is pretty generally felt by now that patients with auricular fibrillation should have continual observation and almost continual medication even though they are about and feeling well. The heart needs a sufficient period of rest between beats in order to avoid fatigue and maintain its functional integrity, and this prolongation of diastole can only be obtained by keeping the heart slowed by digitalis to about 70 beats per minute. For this purpose very small doses do not suffice; at least 10 minims of the tincture, twice daily, are usually necessary.

The question of prognosis I wish most to emphasize. It should not be so gloomy as it is at present. Here are seven patients having this irregularity. They are all comfortable, all but one at work, and some of them are performing exercise of no inconsiderable severity. They are doing this, not only in spite of their irregular heart action, but also in spite of the endocarditis, hypertension or myocarditis which is present in each respective case. Were the irregularity of such serious import as it is often considered to be we could not have patients so free from discomfort as these are for such long periods of time.

Cowan, in his recent book, states that the prognosis in this type of irregularity is always more grave than in comparable cases with sinus rhythm. "The inception of permanent auricular fibrillation is the beginning of the end, though many patients are able to lead quiet lives for a year or two." Lewis, in Osler's System of Medicine, says that fibrillation "loads an already defective muscle with an extra burden, the burden of increased ventricular rate and shortened diastole."

Mackenzie appears to feel less pessimistic as to the prognosis of the arrhythmia. "It is in all probability the extent of the divers associated pathologic conditions which determines the prognosis of auricular fibrillation." He has seen patients who in spite of treatment failed rapidly after the onset of the irregularity, but has "repeatedly seen fibrillation set in and the individual be altogether unconscious of its presence" for a time. He reports the case histories of three patients who were about and living nearly normal lives for six years after the irregularity was noticed, and one for twelve years after.

It is but comparatively recently that we have learned the necessity of continual medication in the presence of auricular fibrillation. Mackenzie, who was the first to make use of it, will be noticed as having given the least severe prognosis. I feel that we should go even further than Mackenzie and say that if the heart is kept slowed by proper treatment the prognosis of auricular fibrillation should be no more grave than that of the associated pathologic condition.

SUMMARY

The continuous irregularity of auricular fibrillation has been looked on as causing a poor prognosis. This is due to stopping treatment as soon as the patient recovers from an attack of acute cardiac failure.

By continuing the digitalis in sufficient quantity to keep the heart slowed to about 70 beats per minute, there will not be a recurrence of the cardiac failure.

Seven such cases are cited in which the patients have remained under treatment without cardiac symptoms for periods of from seven months to three years,

Since these cases are all complicated by conditions of considerable gravity, and since they have performed such considerable physical exertion so long as their heart was maintained at a slow rate, it is concluded that the irregularity, per se, adds little or nothing to the gravity of the prognosis of the individual.

TROMBIDIOSIS

GEORGE MANGHILL OLSON, M.D.
Assistant in Dermatology, University of Minnesota Medical School
MINNEAPOLIS

Trombidiosis, or to use perhaps a better term, trombidiiasis cutis, is a condition of the skin, due to the attacks of the red jigger. It has long been known, although it is evidently infrequently diagnosed, in spite of the fact that hundreds and thousands of cases occur in the United States each summer. In Minnesota there are many hundred cases each summer during the months of July, August and September. Diagnosis is important, as proper treatment relieves the patient of many days of suffering, amounting in some cases to a kind of torture, as Erasmus Wilson[1] has expressed it; and clears up many puzzling cases of skin disease occurring during the summer season. Synonyms are "autumnal erythema" and "harvest disease."

The parasite which causes this condition in Minnesota belongs, in the cases which I have examined, to the species *Trombidium irritans* or *Leptus irritans* (Riley). The hexapod larva only attacks man. The adult jigger has eight legs and is found on bushes, grass, etc., never attacking man. The *Trombidium irritans* or red jigger is also called the harvest bug, harvest mite, mowers' mite, red bug, chigger and gooseberry bug. It belongs to the family of Trombidiidae under the order of Acarina. There are two species in America, the *Trombidium americanus* and the *Trombidium irritans*. The *Trombidium americanus*,[2] the rarer form of the jigger in America, is pyriform in shape. It buries the anterior half of its body in the skin, causing a papular eruption. It attacks children especially, and is often found in the scalp and axilla.

The *Trombidium irritans,* the cause of trombidiosis in Minnesota and probably most of the cases of trombidiosis in the United States, is rounded or oval, and orange red. It is from 0.178 to 0.1855 mm. in length, and from 0.1295 to 0.140 mm. in breadth. It has three pairs of long legs (0.1925 mm.), covered with numerous fine hairs. These hairs are not so coarse or so numerous as those shown in the illustration in Kuchenmeister.[3] Each leg terminates in fine claws. The head shows very clearly the lancetlike piercing apparatus, by means of which the mite gets under the skin.

The *Trombidium irritans* is found here mainly on the grass and bushes near the numerous lakes and streams, especially where the soil is sandy. In Minneapolis the red jiggers are found at the sandy beaches at Lake Calhoun, often attacking the bathers at the Public Baths, causing considerable anxiety to some of them, who fear they have some serious skin disease. They are also quite frequently found at Lake Minnetonka. The red jigger may be found on grass, bushes, corn, clover, grapevines, gooseberry bushes, weeds, blackberry bushes, beans and room flowers. In England the red jigger is found especially in chalky or limestone districts near the sea. The same or a similar parasite is found on the dog, mole, fieldmouse, grasshopper, fly and mosquito.

The red jiggers or mites deposit eggs in or on the ground in the early part of July.[4] As many as 400 of these brown spherical eggs may be found massed together. After a short time the larvae with three pairs of legs appear. Normally they feed on various insects as plant lice, young caterpillars, etc. It is at this stage that they may attack man. In a few weeks, after feeding on some kind of insect, the larva changes to the mature adult mite. The mature mite is parasitic on insects, but does not attack man. The mature mite hibernates in sheltered places or in the soil and appears the next spring. There seems to be but one brood a year.

SYMPTOMATOLOGY

The *Trombidium irritans,* on finding itself on the human body, runs about very actively, and soon selects a place to bore into the skin. By means of its long legs the jigger raises its body and pierces the skin at right angles, and if possible, along a hair follicle. If undisturbed it makes its way until its body is entirely concealed in the skin, where it dies in about a week. In one or two hours the jigger has sunk its head into the skin, and the patient commences to experience a marked itching sensation. If the patient is seen at this time he will unerringly point out the location of every jigger on his body, even if forty or more are present, as in one of my cases. After ten or twelve hours the animal is completely buried in the skin. Usually marked urticarial swelling now occurs, so that often the jiggers cannot be seen, even after very careful examination. Erythematous, urticarial, papular, pustular and eczematous lesions may occur, but urticarial lesions constitute the ordinary form of the disease. The itching is greater than that from any other parasite. Banks[4] states that the red bugs burrow beneath the skin and cause intense itching. "It is an unnatural situation for the mites, and they soon die; but the waiting is not pleasant."

The jiggers are often arranged in semicircles or in the form of a necklace, especially when occurring on the body. The *Trombidium irritans* may be found on the feet, ankles, legs, arms and, especially in women, about the breasts and waist line. Fever may be caused by the jiggers in some cases. Some persons are immune and never suffer from attacks of the *Trombidium irritans,* even when in badly infested places, where their companions are severely attacked. Other persons are frequently attacked even when they stay a short time in places that are not badly infested. The reaction of different individuals also varies, some having marked urticarial lesions, and others simply an erythema about the bite. The urticarial swelling about the bite is markedly increased by rubbing and scratching.

DIAGNOSIS

The disease occurs only in July, August and September. Severe itching, with an urticarial eruption on the arms, legs or trunk, in patients who are near the lakes during these months, is suggestive of trombidiosis. On close examination, the bright orange-red mite can be made out, often in the center of an urticarial papule. Trombidiosis must not be confused with the straw itch due to the *Pediculoides ventricosus*. Straw itch is caused by a similar mite, which, however is white, and does not burrow into the skin. The disease caused by the *Sarcopsylla penetrans* or "jigger flea" does not occur here.

PROPHYLAXIS AND TREATMENT

Prophylaxis consists in keeping away from infested places, and, if exposed, a bath should be taken as soon as possible to remove or drown the mites.

Practically all the books and articles on this subject recommend sulphur ointment, alkaline washes, etc., which certainly give little relief, and do not mention the extraction with a needle and treatment with tincture of iodin, which I have found very effective. If diagnosis is made during the first twelve or twenty-four hours, all the jiggers can be easily removed with a needle. This requires good eyesight and some skill and practice. The jiggers as removed should be placed in a bottle containing alcohol, as some of the jiggers are very active after removal with a needle, and will again bore into the skin if they have an opportunity to do so. After twelve hours, removal is more difficult, because of urticarial swelling, although often many may be found and removed. A peculiar feature of these cases is that the pruritus is so annoying that all patients enjoy the search for the mite, even though considerable bleeding results from the use of the needle. After removal of the mites, relief is pronounced, and the lesions quickly disappear. After each jigger is removed, the spot should be touched with tincture of iodin. This is also the best remedy for the lesions in which the jigger cannot be found. In these cases, painting tincture of iodin on each day gives considerable relief, and within a week the jiggers die and the pruritus ceases.

SUMMARY

1. Trombidiosis or trombidiiasis cutis, the condition of the skin due to the attacks of the red jigger, occurs commonly in Minnesota and probably in nearly all the states of the Union.
2. Trombidiosis occurs only in July, August and the early part of September.
3. Removal of the jiggers by means of a needle and the application of tincture of iodin is the most effective method of treatment.

Knowledge, the Enemy of Quackery.—"No laws will ever be able to prevent quackery, while people believe that the quack is as honest a man, and as well qualified, as the physician. . . . The most effectual way to destroy quackery in any art or science, is to diffuse the knowledge of it among mankind."—William Buchan, M.D., in *Domestic Medicine*, 1783.

THE DETERMINATION OF PULSUS ALTERNANS BY THE SPHYGMOMANOMETER

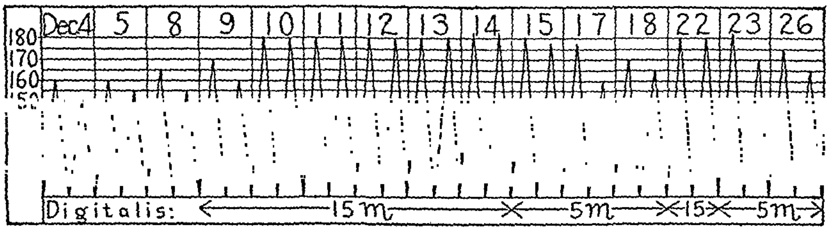
CAROLINE McGILL, M.D.
BUTTE, MONT.

The grave significance of pulsus alternans has been abundantly confirmed. Any simple method for the detection of the condition certainly deserves emphasis. Herrick[1] calls attention to the value of the sphygmomanometer in diagnosing alternating pulse. He says:

> When the systolic pressure is being tested in a patient in whom an alternating pulse is present, a manometer pressure may be reached that cuts off every other beat—the weaker beat—thus halving the rate of the pulse at the wrist.

I have used the same method for some time and have found it reliable and most helpful. The following case illustrates the condition and confirms Herrick's findings. In this case the effect of digitalis therapy on pulsus alternans is well shown merely by following the blood pressure. The blood pressure was taken by the auscultatory method.

Mr. X., aged 53, entered Murray Hospital, Dec. 4, 1914, complaining of marked dyspnea and a severe cough. The family history was negative. The patient had always been exceptionally strong and had lived an active outdoor life. He gave a history of hard chancre on the finger twelve years previously, followed by some skin manifestations. He had thorough mercurial treatment at the time, and three years ago salvarsan, with repeated courses of mercury since. Four years ago the patient received a severe injury to the thorax and since then has been slightly dyspneic. Otherwise, the personal history is negative. The patient was seen at this hospital in 1911; then, the Wassermann was negative. The patient showed rather marked arteriosclerosis and mild chronic nephritis. The blood pressure at that time was 190 mm. Hg. The urine had a specific gravity of 1.010, a trace of albumin, and an occasional hyaline cast. The heart was slightly enlarged.



First four days, one half of beats heard at from 160 to 170 mm. Hg; all the beats heard at 150 to 160 mm. Hg; definite alternation on 15 m minims tincture of digitalis every four hours, the blood pressure rose to 180 mm. Hg and alternation disappeared.

On his present admission to the hospital the patient gave a history of a heavy, severe cold several weeks before, followed by marked dyspnea, and a persistent cough with asthmatic attacks at night. On examination, the patient showed marked myocardial weakness. The heart, both to percussion and Roentgen examination, was very large; the right heart was markedly dilated. The pulse was of fair volume, rather high tension, regular rhythm, rate one hundred per minute. No alternation could be detected by the touch. The patient was markedly orthopneic. There were a few râles at the bases of the lungs. There was slight edema of the ankles and of the eyelids. The Wassermann and luetin tests were negative. The urine was 600 c.c. for the twenty-four hours, specific gravity 1.022, and showed a trace of albumin and an occasional hyaline cast; occasionally there was occult blood. The systolic blood pressure was 160 mm. This, because of the high pressure recorded in 1911, was considered cause for alarm. While the systolic blood pressure was being taken, it was observed that, between 150 and 160 mm., only one half of the beats could be heard; there was typical alternating pulse. The heart showed tick-tack rhythm. The chart shows the condition well and the variation in the pulse when digitalis was administered.

---

[1] Herrick, J. B.: Pulsus Alternans Detected by the Sphygmomanometer, The Journal A. M. A., Feb. 27, 1915, p. 739.

December 9, the highest systolic pressure was 170 mm. One half of the beats came through at this height; all of the beats came through at 160 mm.; all sounds disappeared at 130 mm.; there was definite tick-tack rhythm. On that day the patient was given tincture of digitalis, 15 minims every four hours. Twenty-four hours later the blood pressure went to 180 mm., and all beats went through at this point; the alternation had entirely disappeared; all sounds were gone at 140 mm.; the tick-tack rhythm had disappeared; the second sound was quite sharply accentuated.

December 11, 12 and 13 the blood pressure remained at 180 mm., with no alternating quality present. December 14, the dose of digitalis was reduced to 5 minims every four hours. December 15, there was slight alternating and two days later the condition was marked. The highest systolic pressure was 178 mm., and all beats came through at 160 mm. December 18, the patient was again put on 15 minims of the digitalis. The blood pressure promptly rose and showed no alternation. Two days later the dosage was again reduced to 5 minims, and pulsus alternans promptly returned.

The patient left the hospital, December 26, much improved, but still dyspneic on slight exertion. He soon began moderate work. His doctor reports that the decompensation rapidly returned. By March 1, 1915, there was marked edema of the extremities, with extreme ascites. The patient died March 28, 1915.

CONGENITAL ABSENCE OF PATELLAE

AND OTHER PATELLAR ANOMALIES IN THREE MEMBERS OF SAME FAMILY

GEORGE RUBIN, M.D.
CHICAGO

Although a number of observers have reported cases of congenital absence of patellae, yet out of six standard textbooks of anatomy consulted, only one (Piersol's) calls attention to this anomaly. It says:

> Congenital absence of the patella on one or both sides has been noted in a number of instances, and has in some cases been observed in several members of the same family. The functional disability was slight or altogether unnoticeable.

These observations agree perfectly with the findings in cases here presented.

Another anomaly which exists in two of the three cases is an incomplete development of the thumb nails. The two conditions, namely, absence of patellae and absence of thumb nails, are strangely correlated.

Little[1] collected eighteen cases in a family of four generations in which there were no patellae and no thumb nails. He does not state whether the two conditions coexisted in all the cases or whether some had one and some the other, or how many had both anomalies. It is, perhaps, reasonable to suppose that those conditions existed singly in certain individuals. Heredity is certainly a strong factor in these cases. The three cases in this report show plainly the influence of heredity.

Case 1.—Mrs. W., aged 33, born in France, had unimportant family history except that her mother had no thumb nails. The patient had had rickets in infancy; otherwise the personal history was uneventful until about ten years ago, when a heart lesion was discovered. The lesion is still present and consists of a mitral regurgitation. Except for the murmur, the patient shows no other symptoms. The thumb nails are practically absent. Some horny tissue is present right near the matrix. The right patella is about half the normal size. The left patella is no larger and is displaced, but the latter condition was due to an accident.

Case 2.—Robert W., aged 10, son of Mrs. W., Case 1, also born in France, had rickets, but no other conditions that would have any bearing on this case. While looking over the boy for an eruption which was diagnosed measles, my attention was drawn to the peculiarly shaped knee. The anterior aspect was flat and looked very broad in proportion. On close examination no patellae could be felt. This was later confirmed by roentgenoscopy. The nails of the thumbs were normal.

Case 3.—Henriette W., aged 4 years, born in Chicago, daughter of Mrs. W., Case 1, and sister of Robert W., Case 2, was a marantic baby and has still symptoms of pronounced rickets. There were no other conditions relevant to the case. The knees were examined on account of the findings in her brother and with the same result, that no patellae could be found. It was also verified by roentgenoscopy. The thumb nails are partly developed.

The patella is known as the largest sesamoid bone in the body. The anterior surface is covered by the fibers of the quadriceps extensor tendon, which serves as its periosteum. The development begins in the third fetal month as a cartilaginous deposit. Ossification begins between the second and fifth year. The bone is not fully formed till after puberty or even later. The function of the patella, according to Lickley,[2] is as follows:

> The patella forms a more suitable pulley for movements around the condyle than the tendon itself. A minor advantage is of keeping the upper end of the patellar ligament in a plane well in front of the axis of flexion and extension. There is also a defensive function. The most important function is to supply the quadriceps extensor muscles with a lever on which to act.

As far as can be ascertained by physical examination and observation by physician and individual, no inconvenience is suffered on account of absence of the patellae. Being mindful of the late and possibly delayed ossification, Dr. Van Horn, who has done the excellent Roentgen-ray work in these cases, used especially soft tubes so as to outline any cartilaginous deposits if there were any, and at the same time to see the course of the tendon. The latter could be easily traced.

It seems difficult to explain these anomalies first singly, that is, the absence of patellae or thumb nails, and second, the relationship of the two anomalies.

In the three cases here presented there seems to be present one common condition, and that is rickets. Whether or not that can be assigned as the cause would be difficult to say. Perhaps an intra-uterine rickets with or without postnatal rickets is the cause of these peculiar phenomena.

25 East Washington Street.

To Facilitate Expulsion of the Placenta.—I have often experienced the ease with which the placenta presents itself at the vaginal orifice on requesting the patient to flex the knees and raise the hips slightly from the bed—of course the fundus is firmly grasped before and during the procedure.—J. T. Leland, M. D., Herman, Minn.

PRACTICAL PHARMACOLOGY [*]

(Continued from page 1989)

XXIV

EVACUANTS—*(Continued)*

4. EVACUANTS ACTING ON THE RECTUM

Irritation of the rectum reflexly induces peristalsis in the colon and leads to evacuation of the feces. This rectal irritation may be induced in various ways, the simplest method being a form of local irritation by means of a suppository of soap or glycerin, the injection of a small amount of glycerin or distention by the injection of cold water, or warm water to which soap, glycerin, or other mild irritant, has been added.

If constipation is the result of sluggishness of the movements of the colon, the moderate distention of the rectum by cold water alone will usually suffice to cause a normal evacuation. When the feces have become hard and dry through absorption of an undue amount of their fluid, the normal peristaltic movements are insufficient to drive the intestinal contents along, especially if these have become aggregated into large masses, and the addition of soap to the warm water which is injected slowly, and in sufficient amount so that it penetrates into the colon, aids in softening the masses so that they become at once more plastic and more slippery, and then the peristalsis which is induced by distention of the rectum will suffice to evacuate them.

It is probable that a tube cannot be passed through the rectum into the colon, but if the fluid be injected slowly and with very slight pressure—not more than that exerted by holding the reservoir a foot above the recumbent patient—it will pass gradually into the colon, and may even find its way into the ileum.

Daily stools do not invariably prevent the accumulation of such dry, hard masses of fecal matter, for the colon is so voluminous that soft feces may be forced past such masses which gradually increase in size until they finally obstruct the entrance into the rectum, and cannot be evacuated until they are softened or otherwise broken up.

A warm 5 per cent. solution of sodium sulphate is preferable to water alone for such an enema, because the salt delays the absorption of the water, and permits it to act on the fecal masses for a longer time than it would otherwise.

Glycerin is irritant through its capacity for withdrawing water from the tissues. When introduced into the rectum it sets up peristalsis almost at once by reflex action on the colon. It may be injected in pure form, or added to water or used in the form of a suppository.

Soap may be added to warm water to increase its irritant action on the rectum, or to soften fecal masses as just mentioned, or it may be used in the form of a cone, cut from a piece of castile soap and inserted about 2 inches.

Molasses, oil of turpentine and various other irritants are used as additions to warm water enemas, but they do not require detailed discussion.

DOSAGE

Glycerin as such is injected into the rectum in doses of from 4 to 15 c.c. (1 to 4 fluidrams) or used in the form of a glycerin suppository. When used in the form of an enema it is usually added in quantities of from 15 to 30 c.c. (4 to 8 fluidrams) to from 500 to 1,000 c.c. (1 pint to a quart) of warm, but not hot, water, to be injected slowly at one time.

Soap enemas are made by dissolving not exceeding 5 per cent. by weight of either hard or soft soap in from 500 to 1,000 c.c. (1 pint to 1 quart) of lukewarm water. Cold water, while often efficient, is not so uniformly satisfactory as water at, or slightly above, the body temperature when fecal masses are to be softened.[*]

5. MISCELLANEOUS MEASURES

It has been stated by competent observers that many cases of intestinal stasis or chronic constipation are due to an overdigestion of the food as compared with normal conditions, and that the absence of bulk and necessary moisture retard or otherwise prevent peristalsis.

An effort has been made to overcome these, largely mechanical, factors by the administration of substances which are not in any way affected in the stomach or intestines but which will increase the bulk of the feces, prevent undue absorption of moisture and thus facilitate elimination. It has long been recognized that certain foods, such as fruits and whole wheat bread, containing a comparatively large percentage of indigestible material, will assist materially in establishing regular habits.

Much the same effect can be obtained by the administration of agar-agar and of liquid petrolatum or liquid paraffin.[1] The former has long been used in bacteriologic work as a solidifying material for culture mediums. It is a gelatin-like substance extracted in the East Indies from various seaweeds and has the property of absorbing and retaining water. It prevents the dehydration of feces in the large intestine by holding water tenaciously and thereby serves to increase the bulk of the feces.

Liquid petrolatum or liquid paraffin has long been used to accomplish much the same purpose, though originally it appears to have been given largely with the idea of lubricating the feces. When administered before meals it evidently enters the intestine and is there mixed with the food material, thereby increasing the bulk of the intestinal material, protecting it to some extent from digestion and preventing the absorption of the contained water.

DOSAGE

Agar-agar is given in doses of from 5 to 15 gm. (75 to 240 grains) of the coarsely comminuted substance and may be taken either in water or mixed with food.

Liquid petrolatum should be a colorless and tasteless product, and may be prescribed as "Petrolatum Liquidum Leve or Grave," in quantities of from 15 to 30 c.c. (4 to 8 fluidrams) half an hour or an hour before meals, or in larger doses, from 30 to 60 c.c. (1 to 2 fluidounces) on retiring. Being tasteless and odorless, it can be drunk from a spoon or wineglass, though if preferred, a small amount of oil of peppermint may be added to give a distinctive flavor.

---

[*] This is the twenty-fourth of a series of articles on useful drugs—on practical pharmacology for the general practitioner. As soon as completed, these articles, elaborated by additional subjects, will be published in book form.

[*] Owing to lack of space the materia medica of this group is omitted from THE JOURNAL. It will appear when this series is published in book form.

CHOLAGOGUES

Cholagogues are agents which stimulate the liver cells, causing an increased secretion of bile. The greater part of the bile which is secreted normally disappears during its passage along the intestine, but various drugs which increase intestinal peristalsis, or which interfere with the decomposition of the bile by bacteria, cause it to appear in the feces in increased amounts, and such drugs were formerly termed cholagogues, though most of them have no action on the liver cells. Later investigations have shown that very few drugs except the salicylates and bile itself have any true cholagogue action.

Bile is partly an excretion, containing such waste products as cholesterin and lecithin, but cholagogues are employed only with reference to the influence of bile in promoting the splitting and absorption of fats in the intestine, or as an adjuvant to the action of certain evacuants, such as aloes. Bile also indirectly promotes the digestion of proteins in the intestine, since unabsorbed fats envelop proteins and interfere with the action of digestive enzymes on them.

The secretion of bile varies with the amount of blood which circulates through the liver, and it seems probable that a hormone present in the blood stimulates the liver cells to secrete bile. The introduction of hydrochloric acid into the duodenum causes an increased secretion, and it seems probable that this is due to the secretion which is formed from prosecretin by the acid.

Ox bile, or salts of the bile acids and salicylic acid are the only drugs which are commonly used as chologogues, and their action is feeble at best.

The appearance of fat in undue amounts in the feces suggests the use of cholagogues, but there are seldom any clear indications for their use in adults, except perhaps as an addition to evacuants.

Cholagogues are contraindicated in the presence of jaundice due to obstruction of the bile ducts.

DOSAGE

The dose of the purified ox bile is 0.5 gm. (7½ grains), but much larger amounts may be used. It is best administered in the form of pills, or preferably in gelatin capsules which have been treated with formaldehyd to render them less soluble in the stomach.*

EMETICS

The first stage of the actions of emetics begins with nausea, salivation, increased bronchial secretion, usually sweating, and often a flow of tears. Great muscular weakness attends this stage and the act of vomiting is usually preceded by increased respiration which then becomes irregular and ceases during the vomiting. Usually the saliva drools from the mouth of animals just before emesis occurs.

Vomiting is accomplished by the coordination of a series of actions which include the following: The pylorus is closed, preventing the passage of the contents of the stomach into the intestine; there are antiperistaltic movements of the antrum of the stomach, which move the contents into the fundus; the cardia relaxes while the abdominal muscles contract, compressing the stomach and forcing its contents out through the esophagus and the mouth, and sometimes through the nose. The muscles of respiration are fixed, preventing the aspiration of the vomitus.

The reflexes which control the several active movements and inhibitions of the vomiting act are coordinated through a center in the medulla which lies near that of respiration and which is evidently associated with it physiologically. This center is spoken of as the vomiting center, and stimulation of it either directly or reflexly leads to nausea and vomiting. Occasionally the process is arrested before vomiting actually occurs, and the stage of nausea and general muscular depression may then persist for some time.

There are two types of emetics: those which irritate the sensory nerve ends in the gastric mucous membrane in a specific manner, whereby vomiting is reflexly induced, and those which act directly on the center without coming in contact with the gastric mucous membrane.

Nearly all drugs which violently irritate the mucous membrane of the stomach cause vomiting unless they also induce narcosis or collapse before the emetic action can be developed, and this coordination of the several actions requires some little time, usually from two to ten minutes. Sensory irritation in the stomach does not always cause emesis, and certain drugs induce nausea and vomiting without causing painful stimuli.

The fact that irritants so commonly cause vomiting has given rise to an unfortunate misconception, and it is frequently argued that a given substance must irritate the stomach directly and induce nausea and vomiting if it is irritant when applied to the mucous membranes of other areas, such as that of the nose or conjunctiva. It is true that a substance may be intensely irritant to the nasal mucous membrane and yet be virtually without action on the stomach. This is precisely what one should expect, for one of the functions of the nasal mucous membrane is to protect the air passages against the entrance of foreign bodies, and it accomplishes this by causing sneezing due to irritation of the nasal mucous membrane, hence the latter requires a high degree of excitability, but the stomach is frequently subjected to the action of a great variety of irritant vegetable substances and it acquires a high degree of tolerance to many of them because its function is to retain ingested material.

Many drugs—perhaps a much larger number than is generally supposed—act directly on the vomiting center. When emesis is the object sought, it may be of less importance to determine the seat of the action than it is in those cases in which it is a side action. We do not know the mechanism of the emetic action of ipecac in full,[2] but this does not interfere with our employment of it, whereas it is of the first importance to know whether this effect can be avoided by proper methods of administration when it constitutes a side action of a drug which is used for its systemic effects. If such an action is central it can be avoided only by proper regulation of the dosage, and not merely by the choice of the channel by which it is administered.

It is understood that these remarks apply to the usual conditions observed in the more common diseases, and not to those in which the stomach is extraordinarily irritable, for even the sight of food or the odor of a drug may cause emesis in such exceptional conditions, and a drug which would have no effect under ordinary circumstances might then cause nausea and vomiting. A few drugs which irritate the stomach directly are also capable of stimulating the vomiting center when they enter the circulation in sufficient concentration, this being probably true of sodium salicylate, even when it is administered in dilute solution.

---

* Owing to lack of space the materia medica of this group is omitted from The Journal. It will appear when this series is published in book form.

[2] Recent experiments indicate that the action is at least partly central.

Nausea of various grades and emesis are encountered so frequently as side actions that it may be worth while to point out the cause in some of the cases in which it is commonly encountered: Nearly all readily soluble salts either dry or in concentrated solution (from 5 to 20 per cent.), cause irritation of the stomach; this can be avoided by using them in dilute solutions.

Hydrated chloral is also very irritant to the stomach, and should be administered in dilute solution, and preferably in a bland fluid.

The digitalis bodies without exception, drugs of the picrotoxin group, including wild parsnips, which are frequently eaten by mistake for parsnips, tobacco or nicotin, lobelia, morphin, atropin (occasionally pilocarpin), and related substances stimulate the vomiting center directly when overdoses are administered by any channel.

Emetics were used formerly more frequently than they are at present, the stomach tube being employed now in the majority of cases in which it is desired to empty the stomach after poisons have been swallowed, and even after their subcutaneous injection if they are excreted into the stomach, as morphin is. The stomach tube may be used for the removal of fermenting masses of food, but tenacious curds, undigested meat, and vegetables which have not been masticated properly, may obstruct the tube, in which case emetics are preferable.

The removal of poisons from the stomach requires the use of rapidly acting emetics when the stomach tube is not available. Emetics are also used to remove foreign bodies from the esophagus and from the upper respiratory passages, and to relieve spasm of the larynx and bronchi in asthma, in nondiphtheritic croup and analogous conditions.

It is frequently stated that emesis may facilitate the passages of gallstones through the bile duct, and it is possible that their action is explainable at least in part by their causing muscular relaxation of the duct.

The nauseant stage of the action of the emetics will be discussed when the expectorants are considered.

It is often stated that emetics are contraindicated after corrosive substances have been swallowed, because of the danger of rupturing the walls of the stomach when they have been weakened by the corrosives, but this danger must be remote in the great majority of cases which the general practitioner is called on to treat. The mechanism of emesis which has been described does not depend on the contraction of the musculature of the stomach alone for expelling the contents, and the contractions of the abdominal muscles serve to compress the walls of the stomach against the contents, but this does not subject them to any severe tension which alone can cause their rupture. Certainly the removal or neutralization of caustics demands action, even though it may involve some risk.

EMETICS ACTING DIRECTLY ON THE STOMACH

IPECAC

Ipecac contains two alkaloids which contribute to its actions, one of which is of relatively little importance. These are cephaëlin, to which the emetic action is due for the greater part; emetin, which was so named when it was supposed to be the only active constituent present; and psychotrin, which is unimportant.

The different alkaloids of ipecac have not been studied in great detail, and we are not able to determine in every case to which we may attribute a given action of the crude drug.

Emetin is known to be less actively emetic than cephaëlin, but commercial specimens of emetin certainly cause emesis whether they are administered intravenously or by the mouth. Emetin is said to appear in the stomach after its subcutaneous injection, and since it acts slowly after the latter method of administration, we may infer that its action is partly local, but it also stimulates the center directly after its absorption. The alkaloid is also irritant to the skin and to the mucous membranes of the nose and other regions, and when large doses of ipecac are given by the mouth, a portion passes into the intestine and may cause diarrhea.

Emetin possesses a specific action on the ameba of dysentery, and it alone appears to be responsible for the therapeutic effects of ipecac in that disease. It is also actively destructive to the endameba that is said to cause pyorrhea dentalis and pyorrhea alveolaris.

It is said to cause irritation of the intestinal mucous membrane when present in sufficient amount, causing inflammation with paralysis of the capillaries, much as colchicin and arsenic do, the symptoms resembling those caused by arsenic.

Ipecac causes prolonged nausea which is useful when it is employed as an expectorant, but a disadvantage when it is used as an emetic. Moderate doses do not cause such severe depression as antimony.

ZINC SULPHATE AND COPPER SULPHATE

These two salts act on the mucous membrane of the stomach and cause vomiting after a fleeting nauseant stage, and as nearly the whole of the dissolved salt is removed when vomiting occurs, the side actions are brief and of little importance in most cases.

When emesis is delayed or when it fails to occur, after the administration of copper sulphate, the latter passes into the intestine and causes diarrhea, but it is absorbed very slowly and almost never gives rise to symptoms of poisoning.

Copper sulphate affords one of the best means at our command of combating phosphorus poisoning when that poison is still present in the stomach. Solutions of copper sulphate deposit an impervious coating of copper on the surface of the phosphorus almost instantly when brought in contact with it, and the rapid emetic action of the antidote serves to remove the phosphorus. The deposition of copper occurs with extreme rapidity even when dilute solutions are used, hence large amounts of dilute solutions are preferable to small amounts of concentrated solutions.

Zinc sulphate causes emesis in the same way that copper sulphate does, and it is equally harmless.

Copper sulphate is used for giving a green color to preserved vegetables, and while there is no proof that enough copper can be taken in this way to cause injury the practice is properly prohibited in the absence of proof that even such small amounts are altogether harmless. It is said that fruits dried in zinc-lined trays contain notable amounts of the metal, but there is no evidence that they are harmful on that account.

The nauseant stage induced by copper and zinc sulphate is too fleeting to permit of their use as expectorants.

Antimony and Potassium Tartrate

Antimony and potassium tartrate, or tartar emetic, acts locally on the gastric mucous membrane to induce nausea and vomiting, but tartar emetic is more actively poisonous when it enters the circulation than are the sulphates of copper and zinc, its systemic effects resembling those of arsenic, but fortunately, the poisonous actions of antimony are seldom observed after its therapeutic use as it is seldom used except in small doses as a nauseant.

When large doses are taken and vomiting fails to remove the greater part of such a dose, tartar emetic passes into the intestine and causes severe diarrhea with corrosion of the mucous membranes and absorption into the circulation. In addition to the usual effects which accompany nausea and vomiting, tartar emetic poisoning is attended with copious watery stools, fall of blood pressure, and slow and labored respiration and depression of the central nervous system, ending in collapse and death in rare instances. Some depression of the central nervous system is present even with emetic doses, hence it is not well suited for use in debilitated patients. As little as 0.15 gm. (2 grains) of tartar emetic has caused death when vomiting failed to occur after its administration. When vomiting is delayed for an hour or more after the administration of the usual emetic dose, tannin, lime-water or magnesia should be given to precipitate the antimony and the stomach should be washed, after which active purgation should be induced.

Tartar emetic ointment is irritant, resulting in pustulation, after its application to the skin, the exact mechanism being unknown, though it has been suggested that the double salt is decomposed with the liberation of acid, to which the pustulation is due. Antimony destroys trypanosomes even in very dilute solutions. Nauseant doses of antimony are free from danger.

Other Locally Acting Emetics

Warm water, slight irritation of the pharynx, as by tickling with a feather, alum, common salt, alkalies (including ammonium carbonate) mustard and numerous other means are employed in domestic practice to induce vomiting through their reflex actions, but these hardly require detailed discussion here.

EMETICS ACTING DIRECTLY ON THE VOMITING CENTER

Apomorphin

Apomorphin is the only drug commonly used as an emetic that induces vomiting by its direct action on the medullary center.

When small amounts of apomorphin are injected subcutaneously, nausea and vomiting are induced within a few minutes, these effects being due to the direct action on the vomiting center in the medulla. Less is required by intramuscular injection, and much less intravenously, to induce the action on the center, but the effects of intravenous administration to dogs are somewhat peculiar in that a definite amount is required—neither more nor less in many cases. If less than the emetic dose is given no perceptible effects are observed; if too much is given depression occurs without emesis, and the animal remains refractory for some time. All doses above the minimum effective administered in any other way cause emesis. Much larger doses are required by the mouth than by other channels, and a longer interval ensues before emesis is induced.

In experiments on dogs effective intravenous doses cause emesis within five minutes usually, the emesis is not repeated, and after ten minutes the repetition of the same dose will again produce the same effect as the first. This may be repeated many times with little difference in the effects of the subsequent doses.

Small doses of apomorphin depress the higher centers somewhat as morphin does in animals, depression following very promptly any excitation; but in man the depression of the higher parts of the brain is much less conspicuous, the muscular weakness and other symptoms noted being for the most part secondary to the emetic action. Cushny states that apomorphin has not caused death in man, though it does occasionally cause collapse.

When small doses are administered the nausea is brief and vomiting occurs but once or twice, but if large doses are used vomiting may be repeated frequently for some time, or there may be prolonged nausea and great muscular weakness without actual emesis, with a slight degree of somnolence.

THERAPEUTIC USES

The therapeutic uses of the emetics have been suggested already in the discussion of this subject, but it remains to point out special indications for the choice of the emetic.

When it is merely desired to empty the stomach of indigestible or fermenting food, the simplest emetic is to be preferred, and warm water, mechanical irritation of the pharynx, warm solution of salt, warm mustard water, or other domestic measures suffice. When prompt results are imperative, as in poisoning, the use of the stomach tube is indicated, but if this is not available a promptly acting and dependable emetic such as apomorphin is required, and the emesis may be made more certain by resorting to accessory means, such as irritation of the pharynx with the finger or a feather, or the use of one of the domestic emetics, such as water with warm salt or mustard, should the apomorphin prove ineffective in a few minutes.

When simple emesis is desired for the purpose of removing indigestible food, copper sulphate or zinc sulphate may be used, and accessory measures may be employed at the same time.

Syrup of ipecac is still used to induce vomiting in children in nondiphtheritic croup, when it is desired to secure relaxation of the laryngeal muscles.

The use of emetics to facilitate the passage of gallstones through the duct would seem to depend, partly at least, on the muscular relaxation which accompanies nausea, and vomiting, and as this muscular relaxation is greater with apomorphin than with the other emetics in general use, probably because of a specific muscular action of the drug, it probably deserves the preference for this purpose, just as it is utilized in overcoming the motor excitement in acute alcoholism, which, being abolished, is followed by quiet or sleep. Apomorphin is also used as a hypnotic in small doses.

Ipecac has been used for many years in the treatment of amebic dysentery, its beneficial actions being variously attributed to its tannin and to its alkaloids. There is no reason to doubt that ipecac owes its actions in this condition to its emetin, and since the doses of this alkaloid which are effective in amebic dysentery are not necessarily emetic, this alkaloid has come to replace ipecac largely for this purpose. It may be given orally, intramuscularly or subcutaneously. Halsey recommends the use of pills of ipecac coated with salol, in order that they may pass the stomach undissolved and act on the amebas in the intestine. He calls attention to the fact that the large doses which are required may cause dysenteric symptoms which may be mistaken for the continuance of the disease. Such large doses are frequently combined with opium to prevent the diarrhea, and to permit the more prolonged action of the alkaloid emetin on the amebas.

The use of ipecac, and especially of emetin hydrochlorid, has been recommended in the treatment of pyorrhea dentalis and pyorrhea alveolaris, which has recently been shown to be extremely common among adults. While emetin is capable of destroying the endameba concerned, reinfection is almost certain to occur, hence the drug can hardly be depended on for a permanent cure.

DOSAGE

The average emetic dose of ipecac is stated to be about 1 gm. (15 grains); the expectorant dose is from one-tenth to one-twentieth the emetic. It is used in minute doses—about 0.005 gm. (1/12 grain) as a gastric sedative.

The initial dose for amebic dysentery is 2 gm. (30 grains) and as this amount will usually cause emesis unless steps are taken to prevent it, it should be preceded by a dose of morphin or opium, or it may be directed to be enclosed in gelatin capsules previously treated with formaldehyd or made into pills coated thinly with salol. Unless care is taken in coating the pills an overdose of salol will be administered. It is obviously better to use emetin for amebic dysentery; it should be given in doses of 0.03 gm. (½ grain).

Copper sulphate and zinc sulphate are given in doses of 1 gm. (15 grains) as emetics. They are not used internally for other purposes.

The emetic dose of apomorphin is 0.005 gm. (1/12 grain), injected subcutaneously at intervals of ten minutes until effective, but when used to evacuate poison a somewhat larger dose of apomorphin may be given at once, unless severe depression exists, and emergencies may demand the use of a dose of 0.01 gm. (1/6 grain). It is not recommended as an expectorant, but it is sometimes used for that purpose in doses of 0.002 gm. (1/30 grain).

The hypnotic dose is about 0.002 gm. (1/30 grain) and this or somewhat larger doses may be used subcutaneously in the case of vigorous and violent subjects of alcoholism.

It is stated that 0.004 gm. (1/15 grain) has caused the death of a patient enfeebled by bronchitis, but this must be considered an extraordinary case, and remarkably few deaths have been attributed to it. Apomorphin is practically never given by the stomach to induce emesis, because of the large dose required and the delay in the action.

Antimonials are rarely used for producing emesis at present, but are frequently employed as nauseant expectorants. The emetic dose of antimony and potassium tartrate (or tartar emetic) is 0.03 gm. (½ grain) but this use is not recommended; the expectorant dose is 0.001 gm. (1/60 grain) which may be repeated every hour, or so often as may be necessary to maintain a slight degree of nausea and its accompanying increased secretion, provided the dose is not pushed to the point of causing severe depression. It is obvious that robust patients can stand repeated doses better than those who are already debilitated.*

(To be continued)

New and Nonofficial Remedies

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

CEPHAELINE.—Cephaelina.—Cephaeline is an alkaloid, $C_{14}H_{20}O_2N$, obtained from ipecacuanha root.

Actions and Uses.—These are identical with those of ipecac. It is relatively more emetic and less nauseant and causes relatively more renal irritation and less cardiac depression. It may be employed as an emetic and expectorant.

Dosage.—From 0.005 to 0.01 Gm. (1/12 to 1/6 grain) in pills or as a powder triturated with sugar of milk.

Cephaeline occurs as snow-white, *fine, interlacing* needles, which readily turn yellow. It is soluble in ether and sodium hydroxide solutions, melts at *from 96 to 102* C., and turns brown when heated to 120 C. With Fröhde's *reagent*, a freshly prepared solution of 0.1 Gm. sodium molybdate in 10 Cc. concentrated *sulphuric acid*, it gives a purple color which hydrochloric acid changes to *Prussian* blue.

Non-Proprietary Preparation:

Syrup Cephaeline, Lilly.—A syrup containing cephaeline hydrochloride equivalent to 0.088 Gm. of cephaeline per *hundred* Cc. (⅖ grain per fluidounce). Cephaeline hydrochloride, $C_{28}H_{40}O_4N_2.2HCl+7H_2O$, used in this preparation, is required to be white, practically neutral, completely soluble in about 1.5 *parts* of water or alcohol and also completely soluble in a saturated solution *of barium* hydroxide. Manufactured by Eli Lilly and Co., Indianapolis, Ind.

OUABAIN, CRYSTALLIZED (See N. N. R., 1915, p. 103).

The following non-proprietary dosage form has been accepted:

Ouabain Ampules, H. W. and Co.—Each ampule contains crystallized ouabain, ¼ mg. Prepared by Hynson, Westcott and Co., Baltimore, Md.

The Growth of Surgery.—Rational surgery was one of the gifts of the Greeks, but in the 800 years between Hippocrates and Oribasius few names have survived specially associated with this branch of medicine. Who among us off hand could recall more than two or three in addition to Hippocrates and Galen? Yet in this period scores of important schools flourished with great *teachers* of surgery, men honored in their generation and the glory of their times.—Osler.

SATURDAY, JUNE 19, 1915

VALUE OF THE LUETIN TEST

The luetin test for syphilis, described by Noguchi in 1911, seems to have fallen into disuse after a rather brief trial. Any test so easy and simple as this, and applicable to so prevalent a disease as syphilis, deserves a thorough trial. Hence a summary of the results obtained in a large series of cases is in order, especially as the review leads to the belief that the reaction is one which clinicians should not neglect.

Luetin is the name given to a sterile emulsion of cultures of the spirochete of syphilis grown from six to fifty days on ascitic fluid-agar (anaerobically). The dose is 0.07 c.c. of the emulsion injected intradermally with an equal amount of normal saline solution. The reaction is considered negative when there results only a small wheal surrounded by a slightly hyperemic, indurated zone from 3 to 4 mm. in diameter, which clears up in four or five days. By general consent, three positive types of reaction are recognized, a papular, a pustular and a torpid. The first is an indurated papule with a surrounding hyperemic zone, which appears twenty-four hours after injection, increases in size up to the fourth or fifth day, and then subsides. The second type is a more intense reaction, and is characterized by a pustule instead of a papule at the point of injection. The so-called torpid type of reaction occurs from four to twenty-eight days after the intradermal injection, and usually takes the pustular form. It is observed most frequently in congenital and parasyphilitic cases. Wolfsohn[1] obtained a torpid reaction in six of twelve patients with cardiovascular lesions. The delay in the appearance of this typ[illegible] reaction is, of course, a disadvantage.

In general paresis, 75 per cent. of the tests [illegible] by Ross[2] gave positive results. In 121 cases rec[illegible] by Kilgore,[3] Wolfsohn,[1] Benedek[4] and Board[illegible] 78.5 per cent. gave a positive reaction. These r[illegible] are not so largely positive as those with the W[illegible]mann reaction in paresis, the latter test, according to Robertson,[6] being positive in the blood in 99 per cent. of cases, and in the spinal fluid in 94 per cent. In spite of this, there are points in favor of the luetin reaction. It is sometimes strongly positive when the Wassermann reaction is repeatedly negative. Again, it is specific. The luetin test may be quickly performed by the clinician, whereas the Wassermann requires a skilled technician and special equipment, and, under the best of conditions, errors creep in. Tabulated reports of the luetin reaction in tertiary and congenital lues and in tabes are not at hand, but apparently results are positive in about the same percentage as in general paresis.

It has been suggested that severe constitutional disturbances might follow a strongly positive luetin reaction, but the records lead one to believe that this is uncommon. In 351 cases taken from the records of writers previously quoted and from those of Cohn[7] and Boardman and Gorham,[8] not only were severe reactions absent, but also it is definitely stated that no constitutional disturbances were noted. Local tenderness about the point of injection is of frequent occurrence.

Recently the specificity of the luetin reaction has been questioned, since other substances injected intradermally may give a local reaction which cannot be distinguished from the luetin reaction. Such a substance is emulsion of ascitic agar. Neisser explains this on the ground that the skin in late stages of syphilis is especially sensitive to trauma. He and others believe that this hypersensitiveness is in itself characteristic of syphilis, and that the value of the luetin test is unaffected by it.

Most observers are agreed that in untreated syphilis, primary and secondary, the test is valueless. This is explained on the assumption that the luetin reaction is an allergic phenomenon, and depends on the reactivity of the patient to the proteins of the spirochete. In the first and second stages of syphilis, the disease is so active [illegible] the patient is unable to acquire enough allergi[illegible] er, that is, the antibodies necessary for the reacti[illegible] congenital and parasyphilitic condition[illegible] power of reaction has been acqui[illegible] st is of value.

Ro[illegible] ce of reaction to the luetin and W[illegible] rallel, that is, if the luetin [illegible] here was likewise but [illegible] it in the Wassermann [illegible] reported by others, [illegible] y such similarity [illegible] reaction is not [illegible] n test depends [illegible] roteins.

The advantages of the luetin test lie in the ease with which it is done, the specificity of the positive reaction, and the fact that it may occur when the Wassermann test gives negative results. These facts warrant a general use of the test.

CLINICAL CALORIMETRY IN THE UNITED STATES

The publication of a series of papers on clinical calorimetry[1] in a special supplement to the May issue of the *Archives of Internal Medicine* must evoke a just pride in American medicine. The first contribution gives a summary of the development of calorimetry, particularly as applied to the human subject. Names familiar to all students of physiology—Lavoisier, Regnault and Rieset, Pettenkofer, Voit, Rubner, Zuntz, followed by the Americans Atwater, Rosa, Benedict, Langworthy and Lusk—are brought into their historical relations. The excellent work of the Boston Nutrition Laboratory of the Carnegie Institution of Washington, with its superior equipment of respiration and calorimetry apparatus, has received mention from time to time in The Journal. There Professor Benedict and his numerous collaborators have attempted to establish the fundamental standards of metabolism, not only in normal healthy man, but also in certain diseased states. Elaborate investigations on the energy metabolism in diabetics by Benedict and Joslin, and in infants by Benedict and Talbot, are instances of the substantial contributions which have resulted from the efficient activity of the Boston laboratory.

The first respiration calorimeter ever established in a hospital was made possible by the cooperation of the Russell Sage Institute of Pathology and Bellevue Hospital, New York. Graham Lusk became the scientific director of the institute, and Dr. E. F. DuBois its medical director. The evolution of the bed calorimeter constructed by them represents the successive contributions of a number of earnest young American investigators. The intricate technical details of the elaborate apparatus which enables one to measure the energy metabolism and heat production of man from hour to hour are scarcely of interest to the general reader. The accuracy is such that in observations lasting three or four hours the heat production, carbon dioxid elimination and oxygen consumption, as determined by special tests, can be measured with an average error of 0.9 per cent., 0.6 per cent. and 1.6 per cent., respectively. In the words of Lusk, "The Sage calorimeter reports 'of the disturbances that Nature works and of her cures,' without having, as concerns the sick human being, at any time, in the slightest degree, affected any patient to his disadvantage, but rather having yielded information regarding his condition which has been beneficial in his subsequent treatment."

The average basal metabolism (at perfect rest, from fourteen to eighteen hours after a meal) of the men studied in the Sage bed calorimeter in Bellevue Hospital agrees closely with that found derived from observations on many individuals in the Carnegie Nutrition Laboratory at Boston. The New York investigators have adopted the figure of 34.7 calories per square meter of the body surface as the average heat production of normal men between the ages of 20 and 50 years.

Up to the present time, the most notable contribution of the Sage calorimeter has related to the metabolism of patients with typhoid fever, an investigation in which Dr. Warren Coleman has collaborated. The results indicate clearly that, in this disease, protein, fat and carbohydrate are oxidized to the same or approximately the same end-products as in health, and in their oxidation give off the standard amounts of heat. Therefore the law of the conservation of energy applies to fever patients. The basal heat production rises and falls in a curve roughly parallel with the temperature. At the height of the fever it averages about 40 per cent. above the normal, but in some cases rises to more than 50 per cent. above the normal.

Typhoid patients can store body fat on an abundant diet while losing body weight and body protein. Loss in weight and loss of protein are usually, though not necessarily, parallel. This raises the much-discussed question as to whether or not there is a toxic destruction of protein in typhoid fever. The large excretion of nitrogen in fever has been attributed to the influence of a toxin arising in the disease, and likewise to the increased temperature. The well-known work of Shaffer and Coleman[2] with high calory diets proved that there is no toxic destruction in the sense of a nitrogen loss which cannot be counterbalanced by the nitrogen intake. Typhoid patients can be brought into nitrogen equilibrium when their theoretical calory requirement is enormously exceeded. Recent studies in Müller's clinic at Munich[3] show clearly that normal subjects in whom a minimal nitrogen elimination level is established experienced no increase in elimination when their temperatures were raised to about 40 C.

VALUE OF THE LUETIN TEST

The luetin test for syphilis, described by Noguchi in 1911, seems to have fallen into disuse after a rather brief trial. Any test so easy and simple as this, and applicable to so prevalent a disease as syphilis, deserves a thorough trial. Hence a summary of the results obtained in a large series of cases is in order, especially as the review leads to the belief that the reaction is one which clinicians should not neglect.

Luetin is the name given to a sterile emulsion of cultures of the spirochete of syphilis grown from six to fifty days on ascitic fluid-agar (anaerobically). The dose is 0.07 c.c. of the emulsion injected intradermally with an equal amount of normal saline solution. The reaction is considered negative when there results only a small wheal surrounded by a slightly hyperemic, indurated zone from 3 to 4 mm. in diameter, which clears up in four or five days. By general consent, three positive types of reaction are recognized, a papular, a pustular and a torpid. The first is an indurated papule with a surrounding hyperemic zone, which appears twenty-four hours after injection, increases in size up to the fourth or fifth day, and then subsides. The second type is a more intense reaction, and is characterized by a pustule instead of a papule at the point of injection. The so-called torpid type of reaction occurs from four to twenty-eight days after the intradermal injection, and usually takes the pustular form. It is observed most frequently in congenital and parasyphilitic cases. Wolfsohn[1] obtained a torpid reaction in six of twelve patients with cardiovascular lesions. The delay in the appearance of this type of reaction is, of course, a disadvantage.

In general paresis, 75 per cent. of the tests made by Ross[2] gave positive results. In 121 cases recorded by Kilgore,[3] Wolfsohn,[1] Benedek[4] and Boardman,[5] 78.5 per cent. gave a positive reaction. These results are not so largely positive as those with the Wassermann reaction in paresis, the latter test, according to Robertson,[6] being positive in the blood in 99 per cent. of cases, and in the spinal fluid in 94 per cent. In spite of this, there are points in favor of the luetin reaction. It is sometimes strongly positive when the Wassermann reaction is repeatedly negative. Again, it is specific. The luetin test may be quickly performed by the clinician, whereas the Wassermann requires a skilled technician and special equipment, and, under the best of conditions, errors creep in. Tabulated reports of the luetin reaction in tertiary and congenital lues and in tabes are not at hand, but apparently results are positive in about the same percentage as in general paresis.

It has been suggested that severe constitutional disturbances might follow a strongly positive luetin reaction, but the records lead one to believe that this is uncommon. In 351 cases taken from the records of writers previously quoted and from those of Cohn[7] and Boardman and Gorham,[8] not only were severe reactions absent, but also it is definitely stated that no constitutional disturbances were noted. Local tenderness about the point of injection is of frequent occurrence.

Recently the specificity of the luetin reaction has been questioned, since other substances injected intradermally may give a local reaction which cannot be distinguished from the luetin reaction. Such a substance is emulsion of ascitic agar. Neisser explains this on the ground that the skin in late stages of syphilis is especially sensitive to trauma. He and others believe that this hypersensitiveness is in itself characteristic of syphilis, and that the value of the luetin test is unaffected by it.

Most observers are agreed that in untreated syphilis, primary and secondary, the test is valueless. This is explained on the assumption that the luetin reaction is an allergic phenomenon, and depends on the reactivity of the patient to the proteins of the spirochete. In the first and second stages of syphilis, the disease is so active that the patient is unable to acquire enough allergic power, that is, the antibodies necessary for the reaction. In tertiary, congenital and parasyphilitic conditions, the necessary power of reaction has been acquired, and here the test is of value.

Ross found that the degree of reaction to the luetin and Wassermann tests run parallel, that is, if the luetin reaction was weakly positive, there was likewise but slight deviation of the complement in the Wassermann test. Similar results have not been reported by others, and there is no good reason known why such similarity should exist, since the Wassermann reaction is not dependent on antibodies, while the luetin test depends on reaction of antibodies with specific proteins.

[3] Graham and Poulton: Influence of Temperature on Protein Metabolism, Quart. Jour. Med., 1912, vi, 82. Kocher, R. A.: Ueber die Grösse des Eiweisszerfalls bei Fieber und bei Arbeitsleistung, Deutsch Arch. f. klin. Med., 1914, cxv, 82.

(104 F.) by means of a steam bath, or their heat production was accelerated by very vigorous exercise. This indicates that rise in temperature alone or increase in heat production alone will not cause an increased protein metabolism. In typhoid patients, the situation is otherwise. In the Bellevue cases, food was given which had an energy content much greater than the amount required by the patients as measured directly when they were in the calorimeter. Although the protein content of the diet, as represented by an intake of 15 grams of nitrogen, was ample to establish nitrogen equilibrium had the diet been given to normal men, it did not accomplish this in typhoid fever. Coleman and DuBois insist that it is difficult to see in this anything except the proof that there is an abnormal destruction of protein in typhoid fever. In some cases the protein destruction continued several days after the temperature had reached a low level. It is impossible to escape the conclusion that the destruction of protein is caused by the toxins of the disease.

Doubt has been expressed at times regarding the ability to absorb the large quantity of fat and protein furnished by the high calory diet in the case of febrile patients. In the cases of seven patients reported in connection with the preceding investigations, the average total fat loss was 4.3 per cent. No differences were observed in the percentage absorption of fat in the early and later stages of the fever or up to the end of the first week of convalescence, when the intake was relatively large. The average nitrogen loss in the feces for all the periods amounted to 1.57 grams, or 11.2 per cent. These facts speak well for the alimentary possibilities of the dietary.

No one can read these noteworthy contributions without an appreciation of the splendid spirit of cooperation which has made them possible.

INTERPRETATIONS UNDER THE HARRISON NARCOTIC LAW

Treasury decision 2213, issued June 7 by the commissioner of internal revenue, establishes a new ruling on Section 6 of the Harrison Narcotic Law, the section exempting certain proprietary preparations from the operations of the law. The section provides that preparations and remedies which do not contain more than 2 grains of opium or more than one-fourth grain of morphin or more than one-eighth grain of heroin or more than one-eighth grain of codein, etc., shall be exempt from the provisions of the act. The decision discusses the question as to whether or not "prescriptions" come within the definition of "preparations" or "remedies" as given in the act. The commissioner says:

> The word "preparation" as generally used and understood means ready-made or prepared medicines, and the word "remedies" means that which cures or is efficacious in a specific disease or diseases under all conditions, while the term "prescription" is the written directions or recipe of a physician for the compounding or preparing of a medicine and directions for its use to meet the existing conditions in the case of a particular patient.

Under this interpretation, the commissioner holds that the exemptions in Section 6 do not apply to prescriptions written by registered physicians unless such a prescription is written for a preparation or remedy prepared in accordance with the U. S. Pharmacopeia, National Formulary or other formula, or for a "remedy or preparation" prepared under private or proprietary formula, carried in stock by a dealer, which may be dispensed without a "prescription." Accordingly, the commissioner directs that every prescription containing a narcotic drug in any quantity, unless it is for a preparation prepared in accordance with the U. S. P. or National Formulary, must have indicated on the prescription the name and address of the patient, the date, the name and address of the physician and his registry number. Such prescriptions cannot be refilled, and must be kept on file by the druggist filling them for a period of two years.

This ruling draws exactly the same line in medicinal preparations that exists between ready-made clothing and clothes made to order. A preparation which is put up in accordance with a distinct formula and which is recognized as a definite preparation is exempt, provided it contains less than the minimum quantity of drugs. A physician's prescription, being written to order for an individual patient for a specific purpose, is not exempt, no matter how small an amount of the prescribed drugs it may contain. The practical effect of this decision is, that under it, physicians must include, in all prescriptions containing any opium or cocain or any of their derivatives, the name and address of the patient, the date, and the name, address and registry number of the physician.

At first glance, this decision will doubtless impress physicians as being a discrimination against them and in favor of proprietary preparations. This is true, but it is because the law, as it passed Congress, discriminated against physicians and in favor of "patent medicine." Section 6 of the Harrison law represents the political influence of the "patent medicine" manufacturer in Congress. It should never have been included in the law. Its insertion weakened the law and was due solely to the inability of the members of Congress to resist the pressure from "patent medicine" interests. This section must be repealed; so long as it stands, the Treasury Department has no choice but to enforce it. To use an exemption clause drafted at the dictation of the "patent medicine" interests to exempt physicians' legitimate prescriptions would be an absurdity. There should be no exemptions of any kind under this law. Every preparation of any kind, containing any amount of opium or cocain or any of their derivatives, should be subject to the operation of the law. Physicians have never asked that their prescriptions should be exempt. The demand for such exemption comes solely from the proprietary and "patent medicine" interests; to satisfy these interests, the special exemption was made.

It has often been said that the best way to repeal unwise laws is to enforce them, rigidly and impartially. Section 6 of the Harrison law should be repealed at the earliest opportunity. Until this is done, it should be enforced. Physicians certainly do not wish to have their prescriptions put in the same category as "patent medicine" fakes and frauds. Let the dope-containing "patent medicine" stand on its own merits, if it has any, and let it be distinctly separated from the prescriptions of reputable physicians. With this understanding of the recent decision, the position of the Treasury Department should receive the approval of all physicians.

Another Treasury Decision (T. D. 2414, June 10, 1915), giving the interpretation of the Internal Revenue Bureau on another portion of the Harrison law, has just been made public. This decision has reference to the limitation on the professional prescription and distribution of narcotics by persons whether registered or not. The decision states that registration is limited to certain named persons, and that persons not legitimately engaged in the exercise of their trade or profession cannot legally register under the terms of the act, and has special reference to the prescription and distribution of narcotics on mail orders.

According to the decision, a party must be a legitimate producer, importer, manufacturer, seller or distributor of the mentioned drugs; likewise, a physician, dentist or veterinary surgeon can register under the act and dispense these drugs "in the course of his professional practice only." Such physician, dentist or veterinary surgeon can prescribe these drugs "when he has been employed to prescribe for the particular patient receiving such drugs" and on whom "he shall personally attend in his professional practice only," and then only "when employed to prescribe for the particular person receiving such drugs."

The decision further states that it has special application to those persons not registered as physicians who prescribe or distribute narcotic drugs or preparations on mail orders received from so-called patients or who, under the laws of the state or municipal regulations, are not permitted to practice medicine. This and the decision first referred to constitute two of the most important and far-reaching regulations in regard to the curbing of the indiscriminate sale and use of "patent" or proprietary medicines containing narcotics or habit-forming drugs. The extent of the so-called mail-order prescription cannot be estimated, but this recent treasury decision will undoubtedly have a tremendous effect on lessening this growing evil.

THE EFFICIENCY OF VENEREAL DISEASE CLINICS

While the value of hospitals is not amenable to mathematical measurement or to monetary evaluation, nevertheless it is possible, and justifiable for those interested, either as donors, medical directors or business superintendents, to ascertain what are the returns from the investment of money, time and scientific service. If, for instance, a clinic is dealing with a class of cases for the most part curable, and if, as must be the case, the objects of the clinic's existence are to cure the patients applying for treatment or at least to render their defects noncommunicable, then it is a wise procedure to ascertain the efficiency of the methods employed as measured by the results accomplished.

Interesting data bearing on the value of venereal disease work in New York clinics were recently presented before the health section of the National Conference of Charities and Correction in Baltimore by the superintendent of the Bureau of Public Health and Hygiene of the New York Association for Improving the Condition of the Poor. It is announced that further results of the "efficiency tests" being carried out by this association will be presented at the San Francisco session of the American Medical Association. This investigation, following work of a similar kind in Boston and Cleveland, brought out striking though not entirely unexpected results. A number of the clinics were studied, and, while in most of them the records were so inadequate as to make any conclusions unreliable, in a few it was possible to ascertain with reasonable accuracy such facts as the percentage of total patients making only one visit, the percentage actually discharged as cured, etc.

It was stated that from 30 to 50 per cent. of the gonorrheal patients came to the clinics only once, a situation which would seem to make inevitable a tremendous waste of time of the physicians in charge, in addition to which there must be considered the futility of a single treatment in this disease, and the fact that many of these patients temporarily relieved, at least in mind, continue to circulate freely in the community, subjecting others to infection. In none of the clinics were more than 10 per cent. of the patients discharged as cured, a condition which physicians have long vaguely realized, but on which, by their personal efforts alone, they are powerless to improve.

As pointed out in the Baltimore paper, several things are needed before an improvement can be assured. The clinic records must be kept so that those in charge may know at least what is happening to the patients; there should be a mechanism, based on a "live" and "dead" record card system, and a method of follow up either by card or visit, which would encourage persistence on the part of the patient with the treatment until cured. An intelligent, forceful, yet sympathetic presentation to the patient of the seriousness of the disease, either by the doctor or by a trained social worker, as carried out at the Boston dispensary, will do much to activate a theoretically effective record and follow up system.

In the public health problems of today, there is none more important or urgent than the control of gonorrhea and syphilis. In no field can society less afford to waste energy and funds. The necessity for extension, under either private or governmental auspices, of the mechanism for the control of these most difficult and menacing public health hazards is insistent. Certainly the best utilization on the basis of a 100 per cent. efficiency if possible, of the existing facilities, is demanded on the grounds of efficiency, economy and health.

THE UNIVERSITY OF MINNESOTA AND THE MAYO FOUNDATION

The announcement was made last February[1] that the Mayo brothers of Rochester, Minn., had established the "Mayo Foundation for Medical Education and Research," had endowed it to the amount of $1,500,000 and, with certain conditions, had offered it to the University of Minnesota. The relationship proposed was for a trial period of six years, after which, if it proved satisfactory, the foundation would be placed under the complete control of the university. The offer was considered favorably by the administrative board of the medical school, and referred to the board of regents for action. A special committee of the board of regents was appointed to make an investigation and to report back to the board. An abstract of their report was published last week,[2] and on June 9, the recommendations of the committee were adopted by the regents.

The announcement of the proposed union between the university and the foundation aroused an unexpected opposition, and caused a more lively discussion perhaps than has ever been given to a proposed improvement in medical education and research. This opposition was of positive benefit, however, since it resulted in a most thorough investigation of the Mayo Clinic, the research foundation and the terms of the application, and wide publicity was given to the whole matter. This open appeal to public opinion has not only dispelled the opposition but has also more clearly indicated the advantages of the application. The final effort of the opposition was to secure legislative enactment prohibiting the University of Minnesota from affiliating with agencies outside of the campus. This bill, which would have seriously restricted the university's field of activities, failed to pass, and the fact has come to be clearly recognized that the sphere of activity of the university is the entire state, and not the narrow bounds of the university campus.

From a small beginning, many years ago, the Mayo Clinic has developed until it is now recognized the world over. Its aim has been to bring to its clientele the utmost resources of medical knowledge and skill. In fulfilling this purpose, the scope of the medical research has steadily been extended, and a large amount of material and equipment useful in diagnosis as well as in research has been accumulated. Clinical records particularly have been kept and so cross-indexed as to be readily available for statistical study. This development was directly in line with the plan of the Mayo brothers, first conceived seventeen years ago, to establish a research foundation. That affiliation should be sought with the University of Minnesota Medical School was natural, since for years the clinic has been working in close harmony with that school and has obtained from it many research workers.

Medical education in Minnesota has been unified to a remarkable extent in recent years, and it has been placed entirely under the control of the state university. The reorganization of the medical school two years ago resulted in the withdrawal from undergraduate medical teaching of about forty medical instructors and also of several hospitals in St. Paul and Minneapolis in which clinics had been regularly held for a number of years. This condition might have resulted in the formation of another medical school had not the university grasped its opportunity to develop graduate medical instruction. This provided the way by which the excess of teachers and the splendid material in the hospitals could still be used. At the present time, it is stated, graduate courses are being offered in all laboratory and clinical departments except those of genito-urinary diseases and dermatology, and this work has been arranged in systematic courses leading to the graduate degree of Doctor of Science. Provision has been made also for a number of teaching fellowships in advanced medical research. The acceptance of the proposal to unite the work of the Mayo Foundation with that of the university is directly in line with the policy to retain the control of all medical education in Minnesota, both undergraduate and graduate, in the hands of the state university.

The facilities for research and graduate instruction of the university and of the Mayo Foundation in a large measure supplement each other. Such instruction has been best established at the university in connection with the laboratory branches, whereas at Rochester more work has naturally been done in connection with the clinical departments. This being the case, the rotation of graduate students between the university and Rochester will result in a more thorough and all-round training in both the laboratory and clinical aspects of any chosen specialty. Under the plan proposed, the research work at the two places will be unified and harmonized under the control of the University of Minnesota.

---

[2] The Journal A. M. A., June 12, 1915, p. 2009.

The taking over by the University of Minnesota of this excellent research organization now known as the Mayo Foundation will aid greatly in the development in that state of the highest type of graduate medical instruction and research, such as will compare favorably with, or even surpass, the opportunities to be found elsewhere in this country, or abroad.

THE ACTIVE CONSTITUENT OF THE THYROID

It is nineteen years since Baumann announced his discovery that iodin is a normal constituent of the thyroid gland, and began the series of studies which inaugurated a new era of work on the physiology and chemistry of this organ. Since that time many attempts have been made to determine in what sort of compound the iodin is held in the thyroid, and the relation this iodin compound has to the physiologic and pathologic functions of the gland. While the hypothesis was advanced that the iodin is taken up by the thyroid simply as an adventitious and undesirable chemical impurity, and held where it can do no harm, much as arsenic and other heavy metals are held in the liver, this was not generally accepted; there was too much evidence that the activity of thyroid preparations varies according to the amount of iodin they contain, and some of the crude iodin-containing preparations made from the gland were shown to exhibit many of the physiologic effects that are characteristic of the thyroid itself. The nature of the essential iodin compound, however, was not disclosed easily, and much unsuccessful work has been done in the attempt to repeat with the thyroid the brilliant chemical studies of the active principle of the suprarenal.

Because the aromatic radicals are capable of taking up iodin atoms, the aromatic compounds of the protein molecules (tyrosin and phenylalanin) were strongly suspected of being the nucleus to which the thyroid iodin is bound; but attempts to prove this by analysis, or to construct artificially aromatic iodin compounds with the physiologic effects of the thyroid, were all fruitless. On another page E. C. Kendall,[1] working in the Mayo Clinic, reports the isolation from thyroid glands of a crystalline iodin compound. This substance is believed to be an aromatic compound of iodin, but the aromatic nucleus is not one of the amino-acids existing in proteins, being instead the indol ring. It has exhibited remarkable physiologic activity, and the effects it produces supports the view that it is the chief active constituent of the thyroid gland, so long sought in vain. Of particular interest is the fact that much of the evidence of its activity, as shown by animal experimentation, has been supplemented by observation of its effects on patients with diseases of the thyroid, an important addition to the usual tests on laboratory animals.

While it must be recognized that this work is quite new, and has not yet been corroborated by other investigators, nevertheless the evidence presented seems entirely satisfactory and convincing. Kendall has not yet determined the exact spatial arrangement of the iodin atoms in the indol ring. When this is done, there will be every possibility that the active principle of the thyroid can be prepared synthetically and made available at relatively small cost. In the meantime, the preparation of the active principle in pure form will, if it can be carried out on a commercial scale, make possible much more accurate dosage and better pharmacologic study than can be expected from the crude thyroid tissue with its varying composition and adventitious substances.

Current Comment

PSYCHIC HYPERGLYCEMIA

Much has been written recently about emotional glycosuria and, as might be expected in view of the prominence of blood analysis, about hyperglycemia of nervous origin. Numerous investigators who have employed the highly refined modern technic for the estimation of sugar in the blood have pointed out that various acts incident to experiments on animals are in themselves sufficient to lead to a rise in the sugar content of the circulating medium. Even the manipulations attending the fixation of the subject and the withdrawal of the blood sample have been shown to lead in some cases to an appreciable change in the sugar level of the blood, to which our German colleagues have given the names "Fesselungshyperglykämie" and "Fesselungsglykosurie." The excitation stage preliminary to narcosis with ether, mild operative procedures in the absence of local anesthesia, and similar supposedly insignificant factors, in the belief of a number of investigators, have been demonstrated to leave such evidence of their effect. Loewy and Rosenberg,[1] for example, invariably have found the blood sugar content noticeably higher in animals in which the withdrawal of blood involved some pain. The differences may amount to 100 per cent. At first consideration, these facts strongly suggest the participation of truly psychic influences in the production of the mild hyperglycemia. A prominent rôle has been assigned by some writers to the psychic factor in the "mobilization" of sugar in the organism. Fear, pain and psychic shock enter into this problem. In the pharmacologic institute of the University at Vienna, Morita[2] has tested some of the procedures, such as hemorrhage, mechanical restraint, ether narcosis, diuretics and irritation of sensory nervous elements, which are known to induce a noticeable

hyperglycemia on decerebrated animals. The typical response was still observed in the subjects deprived of their cerebral hemispheres. These facts of experiment, for which the psychic explanation will obviously no longer suffice, may not be strictly comparable with the emotional forms of experiment already mentioned. Nevertheless they raise some new questions in the interpretation of something which has hitherto been supposed to be typically psychic in its origin.

THE MISLEADING NAMES OF NOSTRUMS

The deceptive character of much of the advertising which is attached to the "patent medicine" and nostrum business has become familiar to every thoughtful person, whether he be layman or physician. Frequently the claims made are so preposterous in point of unreasonable statement or exaggerated merit that they might well be classed with other types of submerged humor, were it not for the more serious possibility of the harm potentially hidden. A surprising instance of the penalty which the practitioner is liable to pay for his alliance with the nostrum traffic is furnished in the columns of one of our German contemporaries. The exigencies of the war have awakened a patriotic endeavor to supplant all foreign products as far as possible by materials of home manufacture. This is conspicuously true of proprietary drugs and chemicals. In a formidable list[1] including various products of American origin, such as Angier's Emulsion, Battle's Bromidia, Fellows' Syrup, Listerine, Stuart's Dyspepsia Tablets, Vin Mariani, and other familiar names, supposedly suitable substitutes from German sources are suggested. In the case of one of the foreign nostrums, however, the trade name has evidently been responsible for an amusing bit of advice to the readers of one of the leading medical weeklies. "Prescribe German specialties," the warning states. And forthwith the innocent practitioner is told to replace "Bromoseltzer Emmerson" by some effervescent salt of bromin — to which we may add, What's in a name? In this case 3 grains of acetanilid and 7 grains of potassium bromid to a teaspoonful.

DISPOSAL OF WASTE IN RURAL DISTRICTS

The sanitary disposal of human waste is recognized as one of the most important problems confronting the modern municipality, the successful solution of which has required the exercise of much engineering skill and ingenuity. But for the rural community, the isolated farmhouse, the small settlement, where sewers and unlimited water are as yet unattainable, what device is there that is practicable, that is at the same time cheap, simple, and easily constructed and operated, that is fly and germ proof, that is adapted to the conditions of rural life, and that farmers and dwellers in small towns can be urged to provide with some chance of success? These conditions are all essential, but they are by no means easily complied with. That existing methods or lack of methods of waste disposal in rural districts constitute a real and serious danger has been demonstrated beyond question. Hookworm, typhoid, dysentery, tuberculosis, as well as many forms of intestinal parasites are all spread largely through defective methods of disposing of human waste. Any real or lasting improvement in rural sanitary conditions must be preceded by a radical and permanent reform on this subject. This problem, always urgent, is becoming and will continue to become more important as our rural districts become more densely populated. Bearing on the problem is the United States Public Health Service bulletin, recently issued, on "Safe Disposal of Human Excreta" by Lumsden, Stiles and Freeman. After a general discussion of the problem and its importance, the various types of sanitary privies so far devised are discussed, the manner of construction, advantages and disadvantages, cost, etc., being considered in each case, with illustrations and working plans for their construction. Directions are also given for converting an ordinary insanitary privy into a safe one, as well as directions for cleaning and for final disposition of the contents. This pamphlet should be widely circulated among rural homes. The problem is the same in all parts of the country. It can be solved only by the substitution of intelligent methods for the ones still too commonly in vogue. The question is a vital one to our rural population.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

FLORIDA

Dispensary Opened.—The Jacksonville city dispensary was opened for the first time, May 28. The institution will be opened daily from 10 a. m. to noon, and from 3 to 6 p. m.; and on Sundays, from 10 a. m. to noon.

New City Hospital.—The proposed hospital for Miami is to consist of five units: an administration unit, a ward unit, a surgical unit, a maternity unit and a private ward unit. About $30,000 is at present available for the construction of this hospital, but it is estimated that $10,000 more will be required.

Bill for Inspection of Schoolchildren Passed.—The Florida Legislature has passed an act to protect and conserve the health and lives of schoolchildren and promote their efficiency by providing medical inspection and subsequent medical treatment. The act was signed by the governor and became a law June 4. This law was drawn up by Dr. Oliver J. Miller, health officer of Sanford, and its passage was due in great measure to his efforts. The bill provides for a thorough examination of all schoolchildren of the state, including rural schools, under the direction of the State Board of Health. An inspector is appointed for each county and no physician is to have more than 2,500 children under his care. The bill also provides for a sanitary survey of all school buildings and their environments. This action shows that Florida is keeping well abreast of the times on the subject of public health.

Bill for State Institution for Feebleminded.—Both the senate and house have passed the house bill 249, introduced by Hon. Henry H. McKenzie. This act provides for the appointment of a commission to investigate the need of state institutions for the care of the feebleminded and epileptics and directs the governor to appoint a commission of five persons, one of whom shall be a licensed physician of the state, to investigate this matter. The commission is authorized to call on the physicians of the state and on the authorities of city, county, state and private institutions for statistics to enable them intelligently to report to the next legislature. The act appropriates $500, to be used for the payment of traveling expenses of the commissioners. The bill passed had the endorsement of the state medical association. Among those who have been most active in this propaganda are Dr. Daniel C. Main, Welaka, of the Sisco Fruit Company, a farm colony for epileptics, and Dr. William P. Spartling, Welaka, who has given lectures before various societies showing films of epileptic seizures.

IDAHO

Personal.—Capt. Hubert W. Wilson, Twin Falls, and Lieut. J. Elmer Crouch, Payette, M. C. Idaho N. G., have been detailed to attend the camp of instruction for medical officers at Fort D. A. Russell, Wyo.——Dr. James J. Herrington, Gifford, has been appointed a member of the state board of medical examiners to succeed Dr. Russell Truitt, Cottonwood.

South Idaho Physicians Organize.—The Southern Idaho Medical Association was organized at Twin Falls, June 5, and adopted the constitution and by-laws of the Idaho State Medical Association. The following officers were elected: president, Dr. Joseph N. Davis, Kimberly; vice president, Dr. John F. Schmershall, Jerome; secretary-treasurer, Dr. A. Henry Dunn, Twin Falls, and councilors, Drs. John F. Coughlin, Twin Falls; John M. Minter, Burley, and Edgar L. Simonton, Wendell. The first regular meeting of the association will be held July 13 at Shoshone.

ILLINOIS

Hospital Addition Opened.—In honor of the opening of the addition to St. Anthony's Hospital, Rockford, a dinner was given to the medical staff, June 3. Addresses were made by Bishop Muldoon and Drs. Clifford U. Collins, Peoria, and George P. Gill, Rockford, the first intern at the hospital, and others.

Personal.—Dr. Darwin Kirby, Champaign, was elected president and Dr. Horatio W. Miller, Urbana, secretary of the Twin City Clinical Society, at its meeting in Champaign, June 1.——Dr. Melvin L. Hole has been appointed local surgeon for the Illinois Traction System at Danville.——Dr. Herman P. Harder has been elected president, and Dr. Albert H. Roler, secretary of the Evanston Tuberculosis Institute.——Dr. William F. Bowman, Fishhook, had a narrow escape from drowning while attempting to ford a flooded creek in Brown County. His buggy was overturned and he was swept down stream, but managed to grasp some willow boughs and so remained until assistance arrived.——Dr. Horace B. Dunn, Rockford, has recovered from his recent illness and resumed practice.——Dr. David S. Ray, Cuba, has started on a trip to the Panama Canal and California.

Chicago

Institute of Medicine Started.—The Institute of Medicine of Chicago, a professional society with scientific purposes, was incorporated, June 9, by Drs. Frank Billings, Ludvig Hektoen and William Allen Pusey.

Personal.—Dr. Caroline Hedger returned to Chicago, June 11, after seven months spent in caring for war-stricken Belgians in Europe.——Dr. Joseph Zeisler was elected president, and Dr. Charles P. Caldwell, treasurer, of the Physicians Club of Chicago, at a meeting of the directors held June 10.——Dr. Willoughby Walling was run over by a wagon and seriously injured, June 8.

Local Red Cross Chapter Reinstalled.—The Chicago chapter of the American Red Cross, which was active in Chicago several years ago, was reinstalled June 18, after a reception given to Miss Mabel T. Boardman, Washington, D. C., chairman of the executive committee, and Major-General William C. Gorgas, Surgeon-General, U. S. Army, and chairman of the Red Cross relief board. The reception, which was held at the Blackstone Theater, was given under the auspices of the municipality, the Chicago Association of Commerce, the Chicago Woman's Club, Chicago Medical Society and other civic and commercial organizations.

INDIANA

National Guard Changes.—Major Edson K. Westhafer, Newcastle, has been placed on the retired list.——Major Larue D. Carter, Indianapolis, has been appointed chief surgeon of the state.——Captain Frank W. Foxworthy, Indianapolis, has been placed in charge of Field Hospital No. 1, and ordered up for examination for his majority.——Dr. Edward G. Kyte, Seymour, has applied for examination to the Medical Corps and has been commissioned as first lieutenant.

Personal.—Dr. William F. Willien, Terre Haute, has been appointed secretary of the local board of health in place of Dr. Frank A. Tabor.——Dr. Francis O. Dorsey, Indianapolis, who has been seriously ill at the Methodist Hospital in that city, is reported to be improving.——Dr. George F. Keiper, Lafayette, has been appointed a school trustee of Lafayette.——Dr. James P. Orr, Lebanon, is reported to be seriously ill.

Tribute to Old Physician.—A commemorative dinner was given at the Arlington Hotel, Richmond, June 4, by the medical profession of the Sixth District and other friends to Dr. T. Henry Davis, president and for twenty years a member of the State Board of Health, who for nearly half a century has been a practitioner of Richmond. Dr. Louis F. Ross officiated as toastmaster, Dr. John N. Hurty spoke on "Dr. Davis and the State Board of Health"; Mr. William Dudley Foulke on "The Past and Future of Medicine"; Mr. George H. Knollenberg on "Doctor and Patient"; Hon. D. W. Comstock on "Dr. Davis as a Friend and Citizen"; Dr. D. W. Stevenson on "Dr. Davis and the Profession," and Dr. D. H. Dougan on "The Old Days." Dr. Davis responded, taking for his subject, "Yesterday, To-day and To-morrow." Dr. Davis was presented with a sketch of himself by Henry Mosler and the suggestion was made that the sketch be hung in the high school art gallery or in the city building.

MARYLAND

Flint Club Meeting.—The Flint Club of Baltimore held its three hundred and forty-eighth meeting, June 3. The club was organized twenty-nine years ago and was named in honor of Dr. Austin Flint. The club is a close corporation with a membership of twenty-five and only one elective officer, the secretary and treasurer, who is now Dr. William Caspari. The presiding officer is selected at each meeting.

Alumni Election.—The annual meeting of the Alumni Association of the University of Maryland Medical School, was held May 31, Dr. G. Lane Taneyhill, presiding. The following officers were elected: president, Dr. Albert H. Carroll; vice presidents, Drs. William E. Wiegand, J. C. Clark and George C. Lockard; recording secretary, Dr. Henry O. Reik; assistant recording secretary, Dr. Howard W. Jones; and corresponding secretary, Dr. John I. Pennington.

State Aid for Maryland State University.—At a meeting of the regents of the Maryland State University, June 10, the merger of the Maryland University School of Medicine and the College of Physicians and Surgeons was discussed. The principal business of the meeting was to authorize the treasurer of the university to accept the appropriation made by the legislature for the advancement of medical education. This appropriation is for $15,000 for 1914 and also 1915, together with $5,000 for each year for administrative purposes. The bulk of the total appropriation of $40,000 will be available in October. One half of it is available now.

Personal.—Dr. William S. Thayer, professor of clinical medicine at the Johns Hopkins Medical School, who was operated on recently for appendicitis, has left the hospital. Dr. Thayer has been nominated for one of the five vacancies of the board of overseers of Harvard University. He is one of the ten men nominated by a postcard ballot and stands fourth on the list.——Dr. William Lee Smith, Riderwood, who has been under treatment at the Johns Hopkins Hospital, is much improved and is expected to leave the hospital early in the week.——Dr. Joseph C. Bloodgood, Baltimore, has left for a ten-day trip to Minneapolis and other points in the West.——Dr. Thomas S. Cullen, who was operated on at Johns Hopkins Hospital, May 29, for the removal of gallstones, is reported to be making satisfactory progress toward recovery.

Psychopathic Building Opened.—The John Hubner Psychopathic Building of the Springfield State Hospital, Sykesville, was dedicated June 9. It is a three-story and basement brick structure in the form of a Maltese cross, equipped with laboratories, operating rooms, hydraulic department, continuous baths and many other necessary departments. One wing of the building will be devoted to administration offices. The building was erected at a cost of about $125,000 and is for the care of acute cases of mental disease. The speakers on this occasion were: Dr. Elmer E. Southard, Cambridge, director of the Boston Psychopathic Hospital; Dr. Hugh H. Young, Baltimore, president of the Maryland State Lunacy Commission; Dr. Henry M. Hurd, Baltimore; Dr. Lewellys F. Barker, Baltimore, and Dr. Edward N. Brush, Towson, president of the American Medico-Psychological Association. In appreciation of his twenty years continuous service as a member of the board of managers, Mr. John Hubner, for whom the building is named, was presented with a loving cup.

MASSACHUSETTS

Creel Declines Health Commissionership.—P. A. Surg. Richard H. Creel, U. S. P. H. S., has been obliged to decline the position offered him as health commissioner of Boston on account of his health which has been impaired by long and trying years of service in the tropics.

Amendment to Practice Act.—A letter from Dr. Walter P. Bowers, secretary of the Massachusetts Board of Registration in Medicine, states that the Massachusetts Legislature, in the session just closed, passed an amendment to the medical practice act, which requires that all applicants for registration as physicians in the state must furnish to the licensing board satisfactory proof that they have received the degree of doctor of medicine, or its equivalent, from a legally chartered medical school.

Changes in State Hospitals.—Drs. Willis W. Gleason and Mark Meisner have resigned from the Westboro State Hospital.——Dr. John M. Thompson, Boston, has resigned from the staff of the Foxboro State Hospital.——Dr. James F. McFadden, Foxboro, has resigned from the Psychopathic State Hospital to accept a position in the Foxboro State Hospital.——Dr. Geneva Tryon, Cambridge, Mass., has been appointed assistant physician at the Boston State Hospital for six months.——Dr. Egbert W. Fell, Boston, has been appointed first assistant physician in the psychopathic department of the Boston State Hospital for one month.

Testimonial to Dr. Theobald Smith.—A complimentary dinner was given at the Harvard Club June 2 by about 200 friends and associates to Dr. Theobald Smith, Boston, for twenty years Fabyan professor in Harvard Medical School, who is soon to take charge of the department of animal pathology in the Rockefeller Institute. President A. Lawrence Lowell of Harvard University presided and addresses were made by Drs. Frederick C. Shattuck, Boston; William S. Thayer, Baltimore; Simon Flexner, New York City; former president C. W. Eliot, Drs. William H. Welch, Baltimore; Edward H. Bradford, Boston and Dr. Theobald Smith, Boston.

Neurosyphilis Discussed.—Under the auspices of the trustees of the Boston State Hospital, a symposium on "Neurosyphilis, Medical and Social Progress," was held at the Psychopathic Hospital, Fenwood Road, May 27. The subject was divided into social service methods and results, including methods of investigation, the question of enlightenment of members of the family and patients, family pathographies in respect to syphilis and the economic aspect of the problem. Under the head of clinical diagnosis were considered the question of latent neurosyphilis and paresis sine paresi, types of neurosyphilis and cerebrospinal fluid studies. The third portion of the program devoted to postmortem studies took up the convolutional type in paretics and histologic studies.

Boston Quarantine Transferred.—Surg. Samuel B. Grubbs, U. S. P. H. S., arrived in Boston May 28 and reported to the mayor on the following day. In accordance with an agreement between the city and the federal governments, Surgeon Grubbs assumed charge of the quarantine station at Gallup's Island, June 1. The agreement provides that the federal government shall hold the lease of the station for one year at an annual rental of $1 pending the agreement as to the price for which the station shall be sold by the city; providing also that the federal government shall take over the city employees now in the quarantine service. This will result in Dr. Francis X. Crawford, the present port physician, continuing in service under the new quarantine officer. Dr. Grubbs will reside in Boston and will have his office at the Immigration Station, Long Wharf.

Alumni Meetings.—At the triennial meeting of the Harvard Alumni Association held May 20 Dr. Samuel B. Woodward, Worcester, presided and addresses were made by Gen. Leonard Wood, U. S. Army and others.——The annual meeting and banquet of Tuft's Medical School Alumni Association, Boston, was held May 20 under the presidency of Dr. Herbert A. Donnell, Medford. After the dinner President Herman C. Bumpus, Dr. Charles F. Painter, Boston, dean of the medical school and Prof. Charles D. Knowlton, Boston, delivered addresses and the following officers were elected: president, Dr. James F. Coupal; vice presidents, Drs. Isador H. Coriat, Emma J. Wagner, West Somerville, Sarah E. Coppinger and William H. Greene; secretary, Dr. Andrew P. Cornwall; assistant secretary, Dr. Edith M. Brooks; and treasurer, Dr. Russell B. Sprague, all of Boston.

Personal.—Dr. J. Herbert Young, Newton, has been appointed medical director of the Boston Milk and Baby Hygiene Association, succeeding Dr. Arthur A. Howard, Boston.——Dr. Ernest O. Weinert, Boston, has been recalled to Italy for war duty and sailed June 6.——Dr. William C. Hanson, Boston, has been removed from the position of director of records and publicity for the State Health Commission by Health Commissioner Allan J. McLaughlin and the division has been abolished.——Dr. Thomas F. Harrington, Boston, has been elected deputy state health commissioner by the State Board of Labor and Industry.——Dr. Richard Pierson Strong, Boston, has been elected professor of tropical medicine in the Harvard Medical School, a position for which he had previously received the nomination of the corporation.——Drs. David L. Edsall, Boston and Milton, and Joseph E. Lamoureux, Lowell, have been reappointed members of the Public Health Council of the state.——Dr. Franklin Dexter, Boston, has been appointed director of scholarships in the Harvard medical and dental schools.

MISSOURI

Personal.—Arthur M. Alden, instructor in bacteriology in the St. Louis University, has been appointed pathologist to the Santo Tomas Hospital, Panama City, Panama, and sails from New York, next week.——Dr. Fabian L. Pratt, Kansas City, sailed from New York May 29, to enter the French Medical Service.——Dr. Joseph M. Yater, Nevada, has been appointed a member of the board of regents of the State Normal School, Springfield.——Dr. James Stewart, St. Louis, is making a good recovery after an operation performed May 3, at the Jewish Hospital.

State Health Board Upheld.—The Supreme Court of Missouri rendered a decision June 1 upholding the right of the State Board of Health to revoke licenses of physicians who write prescriptions for liquor in "dry" counties. The case before the court was that of Dr. A. M. Conway, Columbus, who is reported to have written 778 prescriptions for liquor during February and March, 1910, and is said to have received twenty-five cents each for these prescriptions, which contain no ingredients except whisky. This case was tried in the Boone County Court and resulted in conviction and a short time later the State Board of Health revoked the license of Dr. Conway and an appeal was taken to the Supreme Court with the result as stated above.

Estate Goes to Hospital.—The late Mr. George D. Barnard, donor and beneficiary of the Barnard Free Skin and Cancer Hospital of St. Louis, left an estate of $2,000,000 well invested in first-class business securities. After annuities to his widow and various institutions amounting to about $50,000 are paid, the residue of the income goes to the Barnard Free Skin and Cancer Hospital. After the expiration of the annuities, through the death of the various legatees, this institution will receive the income from the whole estate. About $16,000 a year, consisting of small sums to various local institutions, will be a perpetual charge against the estate. The Barnard Free Skin and Cancer Hospital has had up to this time an income of over $30,000. This, together with that from the Barnard estate, will enable the institution to extend its investigations along much broader lines than it has been possible to pursue in the past.

Health Tests for Waiters and Cooks.—The Medical Society of the City Hospital Alumni of St. Louis, has adopted resolutions setting forth that on account of the prevalence of communicable diseases among employees in kitchen and dining room service in St. Louis, every employee found to be diseased should be excluded from service; that the Division of Health should ascertain the presence of any disease of any employee in eating places; that the director of the Department of Public Health should consider the public needs in this direction and secure the enactment of the appropriate legislation to give authority to the Division of Health to initiate inquiries and conduct examinations; that all kitchen and dining room help, before employment therein, shall be required to undergo a physical examination under the direction of the Department of Health and that no one failing to secure a clean bill of health, shall be eligible to employment. These resolutions were placed in the hands of the committee on municipal affairs and public health, with instructions to arrange for a conference with city officials touching the details of the proposed resolutions.

NEW YORK

Hospital Celebrates Anniversary.—St. John's Hospital, Long Island City, recently celebrated its twenty-fourth anniversary, on which occasion Dr. James J. Walsh, New York City, delivered the address.

Child Welfare Day.—The State Department of Health has designated Sunday, June 20, as Child Welfare Day. Pastors of all denominations have been asked to cooperate by preaching or giving short talks on child welfare and the prevention of infant mortality.

Personal.—Syracuse University conferred the degree of LL.D. on Dr. Henry L. Elsner, Syracuse, June 9.——Dr. C. Floyd Haviland, first assistant physician at the Kings Park State Hospital, Long Island, has been appointed superintendent of the Connecticut State Hospital, Middletown, vice Dr. Henry S. Noble, deceased.

Tuberculosis Camp Opened. — The eighth season of the open-air camp of the Buffalo Association for the Relief and Control of Tuberculosis opened June 1. Only ambulant cases are accepted at this camp. The camp will accommodate about sixty full-time patients and many additional day patients. Dr. Francis J. Lennon continues as medical director and is assisted by Dr. John G. Stowe.

Features of Alumni Meeting.—At the annual banquet of the Alumni Association of the medical department of the University of Buffalo, June 3, recognition was given to Dr. Peter W. Van Peyma, Buffalo, of the class of '72, teacher and clinical professor of obstetrics in the university for thirty years and the representative of the Medical Alumni on the University Council, who retires this year. The graduating class presented a portrait of Dr. Van Peyma to the university to be hung in the college library. At the meeting steps were taken for the establishment of an alumni fund to be used for the advancement of teaching and research work in the institution. Among the many interesting features of the meeting were the surgical diagnostic clinic held by Dr. George W. Crile, Cleveland, and the alumni oration on "Cerebral Localization with Especial Reference to the General Practitioner," by Dr. William House, Portland, Ore.

New York City

Health Department Investigating Wall Street.—Dr. Sigismund S. Goldwater, Commissioner of Health, has issued an order to the sanitary bureau and the division of occupational diseases to investigate sanitary conditions in the office buildings below Fulton Street. The inspection will be similar to that undertaken in factories and sweatshops throughout the city.

Drug Victims Fill City Prisons.—At a recent conference on crime and environment, Dr. Katherine B. Davis, Commissioner of Corrections, stated that on March 1, 1914, there were 4,647 persons in the correctional institutions of New York City, while on March 1, 1915, there were approximately 7,500, an increase of almost 50 per cent. Dr. Davis attributes this increase to the drug crusades of the past fifteen months which have increased the number of commitments of users of habit-forming drugs as well as of persons convicted of trafficking in narcotics.

Patients to Pay If Able.—The city has decided to operate the Municipal Tuberculosis Sanatorium at Otisville on Shawangunk Mountain, on a new plan. Heretofore, it has been the practice to receive all regularly admitted persons as free patients, but from this time on, patients admitted to the institution will be put on the same basis as those who seek to receive treatment in other city hospitals. Inquiry will be made as to their financial ability to make payment and those who are found to be able to pay, will be given the opportunity. Three uniform rates have been decided on, $3.50, $7.00 and $10.50 a week. Patients unable to pay and otherwise suitable as cases for admittance, will be admitted and treated as before, free of charge.

To War Against Strong Drink.—Dr. Sigismund S. Goldwater has declared officially that he is about to initiate a campaign against the use of spirituous liquors in New York City. He has sent a mandatory letter to the Advisory Council of the Department of Health asking for the immediate organization of a committee to put such a campaign in force. Dr. Goldwater acknowledges that he has undertaken a "big job" but contends that the regulation of the liquor traffic is a duty of the Health Department since such a large proportion of the poverty, crime and sickness of the city can be traced directly to the influence of alcohol. It is stated that the campaign will be one that will appeal to popular fancy and will have as its slogan "Get on the water wagon."

NORTH CAROLINA

Dinner to Chicago Physician.—Dr. Noble S. Heaney, Chicago, was given a complimentary dinner by the Buncombe County Medical Society at Asheville, May 21.

Correction.—Dr. John A. Williams, Greensboro, announces that the report in The Journal that he had a stroke of paralysis in New York City, is incorrect. Dr. Williams reports that he is in good health.

State Hospital Report.—The State Hospital for the Insane, Morgantown, reports a residence population of 1,404. The opening of the new colony building last month gave additional room and sixty-two patients have already been admitted to the building.

Institution for Sick Babies.—A donor who does not desire his name to be made public, has tendered $20,000 to the city of Wilmington, to provide an institution for the care of infants whose home conditions are not sufficient for their care when ill. The donor announces that the fund will be available as soon as a sufficient amount to guarantee maintenance charges is secured.

Dean Confers Degrees in Virginia.—Dr. John C. Montgomery, dean of the North Carolina Medical College, Charlotte, attended the recent commencement of the Medical College of Virginia, Richmond, to confer the degrees on the students of the North Carolina Medical College who matriculated before the amalgamation of the institution with the Medical College of Virginia.

Canvass of Derelict Counties.—Dr. J. R. Gordon, chief of the Bureau of Vital Statistics of the State Board of Health, has made a special canvass of certain derelict counties of the state in order to secure more efficient and complete reports of births and deaths. The health department is not assured that all births are being reported while the death records are believed to be fairly correct.

Personal.—Dr. Lewis B. McBrayer, superintendent of the State Sanatorium for Tuberculosis, has been appointed postmaster of Sanitarium.——Dr. Claude O. Abernethy, Raleigh, has returned after a period of postgraduate study in New York City.——Dr. William K. Reid has been elected city physician of Charlotte, and Dr. Eugene P. Gray, city physician of Winston-Salem.——Dr. Carl V. Reynolds has been reelected health officer of Asheville.

PENNSYLVANIA

Optometry Bill Vetoed.—On June 3, Governor Brumbaugh vetoed the House bill to create a separate bureau for licensing optometrists, to practice in Pennsylvania. A similar bill was vetoed earlier in the session and with certain amendments it was again passed by the assembly.

State Health Bureau Wins Medal.—On June 10, recorder of deeds Ernest L. Tustin, a member of the Pennsylvania commission to the Panama-Pacific Exposition, announced that the grand prize for the best health department had been awarded to Pennsylvania with personal praise for Dr. Samuel D. Dixon, state commissioner of health.

Philadelphia

Resignation of Assistant Director.—Alexander M. Wilson, assistant director of the Department of Health and Charities, has resigned, as he has been appointed director of investigations of the department of charities in New York City, a position paying $4,000 a year, the same salary he has been receiving here.

Donation of Surgical Instruments Requested.—The French Relief Committee of Philadelphia announces that surgical instruments are urgently needed in the smaller hospitals in France. An appeal is made to surgeons throughout the United States to donate for this purpose such instruments as they can spare, to be forwarded to France. Such instruments may be sent to the French Relief Committee, 708 Sansom Street, Philadelphia.

Personal.—Dr. Samuel McClary, III, has been elected assistant professor of surgery in the Medico-Chirurgical

College of Philadelphia.——Dr. R. Tait McKenzie, director of physical education at the University of Pennsylvania, sailed for London, May 29, where he will take charge of a new physical examination department, established by the British government.——The board of city trusts, on June 9, appointed Dr. Paul B. Cassidy and Dr. Oscar G. Flegley, respectively, as first and second clinical assistants and Dr. Harry Judge as resident to the Wills' Eye Hospital.——Dr. Ella B. Everitt has been elected president of Wilson College for Women at Chambersburg.

To Reduce Infant Mortality.—Greater efforts than ever are being made this summer to reduce infant mortality. June 5, Dr. Ziegler, director of public health and charities, announced the appointment of fifteen nurses to the division of child hygiene. The full number of nurses for the work among children will be increased to forty for the work during July. Last summer there were about eight nurses engaged in this work. The nurses are to be paid out of an appropriation of $7,500. They will make a house to house visit which will bring home to patients by actual contact the teaching and necessity for scientifically safeguarding the health of the children.

Surgical Unit Sails.—Dr. J. William White and the University of Pennsylvania medical unit, which is to take charge of an entire floor of the American Ambulance Hospital at Neuilly-sur-Seine, during July, August and September, sailed from New York, June 12, on the American liner, *St. Louis.* Dr. James B. Hutchison will be the chief surgeon, and the party numbers fourteen, including four nurses. Dr. Thomas G. Aller is the dental surgeon and Dr. David M. Davis of Johns Hopkins University will have charge of the bacteriologic research. At least $10,000 will be required to maintain the university unit, $7,000 of which has already been collected. No member of the party will receive a salary and most of the physicians are paying their expenses. Six dental surgeons who were unable to secure passage on the *St. Louis* will sail for France on Saturday, June 19, and will join the contingent at the American Ambulance Hospital.

TENNESSEE

Appropriation for Tuberculosis Hospital.—The house of representatives on May 7 passed the bill appropriating $50,000 for a state hospital for tuberculosis.

Free Dispensary for Chattanooga.—At a meeting held in Chattanooga, May 10, final plans for the establishment of a free clinic or dispensary were developed. The amount required for the establishment of the clinic will be about $2,500. The work is expected to be affiliated with that of the Associated Charities and Erlanger Hospital.

Witherspoon Club Banquet.—The annual banquet of the Witherspoon Club Society composed of the leading members of the senior class of the medical department of Vanderbilt University, Nashville, was held May 8. Dr. John A. Witherspoon, Nashville, in whose honor the club was named, was present and delivered an address.

Board of Preliminary Examiners.—Legislation recently obtained provides for a board of preliminary examiners to examine all applicants for license to practice the healing art as to their literary qualifications. Unless candidates are found to be duly qualified, they will not be permitted to take the examination for license to practice. The board consists of three members, and those appointed, respectively, for six, four and two years, are Profs. I. S. Hudson, Nashville; C. C. English, Bristol, and J. W. S. Rhea, Memphis. All members thereafter will be appointed to serve for a term of six years.

Personal.—Dr. Leonard W. Edwards, Nashville, has been appointed physician to the Nashville Penitentiary.——Dr. J. A. B. Ward, Clarksville, was seriously injured by the overturning of his automobile, recently.——Dr. Isadore Lewinthal has been reelected president of the State Board of Charities.——As the result of a competitive examination, Dr. Lucius P. Brown, state food and drug commissioner of Tennessee, has been appointed director of the bureau of inspection of the Department of Health of New York.——Dr. James K. Goodloe has been appointed city prescriptionist of Nashville, succeeding the late Dr. Peter Hager.——Dr. T. P. Holman, Fayetteville, is reported to be critically ill as the result of a cerebral hemorrhage.——Dr. John D. Brewer, Newbern; Reese W. Patterson, Knoxville, and Young W. Haley, Nashville, have been appointed members of the State Board of Examiners for Nurses. There are also two nurses on the board.

TEXAS

Medical College Closed.—It is reported that the Southern Methodist University of Dallas will not reopen its medical department next fall owing to the lack of adequate finances.

Medical Building.—A building is to be erected in Dallas especially for the use of physicians by Drs. Raleigh W. Baird, Harold M. Doolittle, Alfred I. Folsom and Robert B. McBride, all of Dallas.

New Hospital.—The new hospital for the Masonic fraternity near Arlington is completed and will be ready for occupancy this month. The institution will accommodate about thirty patients and will cost, when completed, about $20,000.

Personal.—Dr. Byron F. Kingsley, San Antonio, has been reelected president and Dr. George W. Sims, San Antonio, has been elected vice president of the Bexar County Humane Society.—Dr. Marvin P. Stone, Dallas, has been appointed surgeon-in-chief of the Masonic Hospital at the Home for Aged Masons, Arlington.

Quarantine Station Moved.—The office of Surg. Robert L. Wilson, surgeon in charge of the United States Quarantine Station at Galveston, has been moved from the old postoffice building to the [illegible] Pelican Spit. The new buildings are [illegible] and will be formally opened about July 1.

Appropriation for State Board.—The House of Representatives has passed an appropriation for the State Board of Health carrying a total of $141,840.00 for the biennium. An amendment was also adopted adding $4,000 a year to this appropriation for the establishment of a course in hygiene, sanitation and improvement of public health in public schools of the state, under the direction of the State Board of Health.

Federal Control of Quarantine.—Colonel Walter Gresham of the Deep Water Committee of the Galveson Commercial Association laid before the governor and the finance committees of the legislature a proposition to vest the authority of port quarantine in the federal government instead of the state. This, it is alleged, will mean a saving to Galveston shipping of from $15,000 to $20,000 a year and a more thorough and efficient service in quarantine administration.

Addition to Teaching Hospital.—An official report states that a woman's addition to the John Sealy Hospital has been erected at a cost of $125,000, the money being donated by Mrs. R. Waverly Smith and her brother, Mr. John Sealy of Galveston and that a new nurses' home, costing $90,000 and accommodating fifty-five nurses has been erected by the University of Texas at Galveston, in close proximity to the John Sealy Hospital. This is the teaching hospital of the Department of Medicine of the University of Texas.

Embargo Lifted.—A proclamation was issued by the governor May 28 raising the embargo on cattle from all except the states of Connecticut, Delaware, Illinois, Indiana, Iowa, Kentucky, Maryland, Massachusetts, Michigan, New Hampshire, New Jersey, New York, Ohio, Pennsylvania, Rhode Island, Virginia, West Virginia, Wisconsin and the counties of Butler, Cowley, Sedgwick and Sumner in Kansas. The proclamation also provides twenty-two points of entry at which cattle may be shipped from the border of Mexico into the United States, under stated restrictions.

WASHINGTON

New Hospital.—At Walla Walla and Waitsburg, April 21, $12,702 was subscribed for the new St. Mary's Hospital, Walla Walla. The Sisters of Providence have already $62,000 available and only a little more than $10,000 is now required before the work on the buildings can be commenced.

CANADA

Ambulance Donated.—Messrs. A. Davis and Son, Kingston, Ont., have donated a motor ambulance to Queen's Stationary Hospital.

Nurses for Convalescent Homes.—The Convalescent Homes being established throughout Canada to attend to wounded and invalid soldiers are to have the services of the Victorian Order of Nurses.

For Overseas Service.—The following names are mentioned in connection with the Base Hospital for overseas service, donated by the Ontario government: Drs. Herbert J. Hamilton, Rowland B. Orr, Herbert A. Bruce and Harry B.

Anderson. These are all well-known practitioners in Toronto, and if finally appointed will be given the rank of lieutenant-colonel.

Reciprocity for Druggists.—The Ontario Pharmaceutical Association have almost completed negotiations for reciprocity with the Pharmaceutical Association of Australia. A deputation of druggists representing the whole Dominion is to wait on the government of Ottawa in recognition of the pharmacists who are at the front in the military training camps. The druggists want commissions for their members the same as for dentists and veterinary surgeons.

Medical Roster for Overseas Duty.—The Canadian Relief Committee in Toronto have endorsed the proposition to form a roster of medical men for overseas duty. The suggestion is to accept in turn, as required, a limited number of members of the medical profession for six months' duty. As hundreds are anxious to take part in this particular work, it is felt that some arrangement could be made whereby engagements for indefinite periods would be done away with.

Will Protect Practices of Physicians at Front.—At the thirty-fifth annual meeting of the Ontario Medical Association a resolution was adopted expressing the appreciation of the association that so many of its members have responded to the call of the Empire or have entered on active service, and expressing the intention of the association to look after the work of these physicians during their absence and to see that their practices are retained and restored to them on their return.

Personal.—Dr. Hibbert W. Hill, who has been on duty with the State Board of Health of Minnesota for some time, has been renamed as director of the Institute of Public Health of London, Ont.——Dr. David H. Dowsley, formerly of Ottawa, is believed to have been lost on the *Lusitania*.——Dr. Angus W. McPherson, Peterboro, who was recently elected president of the Ontario Association of Health Officers, is at present in England on overseas duty.——Dr. James D. MacDonald, Huntsville, Ont., has been chosen liberal candidate for the constituency of Muskoka, Ont.

GENERAL

Louisiana Health Car Goes to San Francisco.—The educational hygiene exhibit cars of the Louisiana State Board of Health will be taken to San Francisco. The cars leave New Orleans on the morning of June 16, and are scheduled to arrive at San Francisco some time on the 20th. An opportunity is, therefore, afforded to those who attend the meeting to see this widely known exhibit.

Army Medical School Graduation.—At the annual commencement of the United States Army Medical School, Washington, held in the auditorium of the school, May 31, thirteen graduates received their diplomas from Assistant Secretary of War Breckenridge. The Hoff memorial medal was awarded to Lieut. Harry D. Offut, M. R. C., U. S. A., Maryland, by Col. John Van R. Hoff, M. C., U. S. A., Washington (retired), and the Sternberg medal was awarded Lieut. Raymond E. Scott of Washington. The principal address was made by Lieut. Reynold Webb Wilcox, M. R. C., U. S. A., New York.

Bequests and Donations.—The following bequests and donations have recently been announced:

Sibley Memorial Hospital, Washington, Pa.; Benjamin A. Haywood Memorial Dispensary and Pathological Laboratories, donation by Mrs. Elizabeth E. Haywood, Sheran.

Jefferson Medical College, Philadelphia, for the endowment fund, $100,000, subject to the raising of an equal amount by the alumni of the institution; Home of the Merciful Saviour for Crippled Children, Philadelphia, $1,000, and a contingent bequest of one-half of the residue of the estate, the principal to revert in equal parts to the University and Episcopal hospitals, by the will of Josephine Lewis.

Episcopal and St. Timothy's hospitals, Philadelphia, each $1,000, by the will of Dr. John L. Brumley.

Methodist Hospital, Philadelphia, $1,000 by the will of Martha Moore.

St. Timothy's Hospital, Philadelphia, a contingent bequest by the will of Charlotte M. King.

Conference on Race Betterment.—The Second National Conference on Race Betterment will be held at San Francisco from August 5 to 8. During the first week in August the American Genetic Association, American Association for the Advancement of Science, American Anthropological Association, American Association for the Study of Feeble Minded and the American Social Hygiene Association will hold congress in and near San Francisco. It is the intention of the Conference on Race Betterment to cooperate as far as possible with the above-named organizations. The headquarters of this conference will be on the exposition grounds, and the sessions for the greater part will be held at the exposition.

Aid for Belgian Physicians.—The report of the treasurer of the committee of American physicians for the aid of the Belgian profession, for the week ending June 12, 1915, lists the following contributions:

New England Hospital Medical Society, Boston, Mass.		$ 30.00
Aux Plaines Branch of Chicago Medical Society, Maywood Ill.		44.00
Vigo County Medical Society, Terre Haute, Ind.		25.00
Dr. Jacob Schwinn, Wheeling, W. Va.		10.00
Dr. John Bryant, Boston, Mass.		10.00
Drs. Robert J. and John L. Sagerson, Johnstown, Pa.		10.00
Dr. Catherine H. Travis, New Britain, Conn.		2.00
Dr. George B. Lake, Manila, P. I.		2.00
Dr. M. J. Kenefick, Algona, Ia.		10.00
Dr. E. W. Link, Palestine, Tex. (Second contribution)		10.00
Receipts for the week ending June 12		$ 153.00
Previously reported receipts		7,159.00
Total receipts		$7,312.00
Disbursements for the week ending June 12:		
140 standard boxes of food at $2.28	$ 319.20	
Previously reported disbursements:		
1,625 standard boxes of food at $2.20	$3,575.00	
1,274 standard boxes of food at 2.30	2,930.20	
213 standard boxes of food at 2.28	485.64	
Total disbursements		7,310.04
Balance		$ 1.96

F. F. Simpson, M.D., Treasurer,
5 Jenkins Arcade Bldg., Pittsburgh, Pa.

Subscription Faker Arrested.—The Periodical Publishers' Association has succeeded in arresting one Floyd Maxwell, who, it is said, has for some time been soliciting from physicians subscriptions to such magazines as the Literary Digest, and the Current Opinion, offering medical books as premiums. The Journal has on several occasions published warnings against a scheme of this nature, especially as several physicians have notified The Journal that they had been victimized. Those who have been caught by this man should send the evidence to the Chief of Police, Oshkosh, Wis., in which city Maxwell was arrested, to aid in prosecuting the case. The fact that this particular individual has been arrested should not, however, encourage physicians to relax their watchfulness. Such schemes are continually being foisted on physicians by various subscription fakers, and it is well to be very cautious of too bountiful offers.

Recent Regulations Under the Harrison Narcotic Law.—The following are recent regulations under the Harrison Narcotic Law considered editorially in this issue of The Journal, page 2070.

Meaning of Section 6

. . . The question arises whether or not "prescriptions" come within the definition of "preparations" or "remedies," as given in the act. The word "preparations," as generally used and understood, means ready-made or prepared medicines and the word "remedies" means that which cures or is efficacious in a specific disease or diseases under all conditions, while the term "prescription" is the written directions or recipe of a physician for the compounding or preparing of a medicine and directions for its use to meet the existing conditions in the case of a particular patient.

It is, therefore, apparent that the exemptions in Section 6 of the Act as interpreted in Treasury Decision No. 2172, relating to "preparations and remedies" containing not more than the specified quantities of the drugs enumerated, do not apply to "prescriptions" written by registered physicians calling for any quantity of the narcotic drug, unless such "prescription" is written for a "preparation or remedy" prepared in accordance with the U. S. Pharmacopeia, National Formulary, or other formula, or for a "remedy or preparation" prepared under private or proprietary formula, carried in stock by a dealer, which may be dispensed without a "prescription."

Every "prescription" therefore, containing a narcotic drug in any quantity, with the exemptions noted, must have indicated thereon the name and address of the patient, the date, the name and address of the physician, and his registry number. Such "prescriptions" cannot be refilled and must be filed for a period of two years.

Mail Orders

. . . The fact that registration is limited to certain named persons indicates that there must be a power of discrimination vested in collectors of internal revenue as to who shall be registered and from whom special tax may be received. Therefore, persons not legitimately engaged in the exercise of their trade or profession cannot legally register under the terms of this Act. For example, a party must be a legitimate producer, importer, manufacturer, seller, or distributor of the aforesaid drugs, and likewise a physician, dentist, or veterinary surgeon can register under this act and dispense these drugs "in the course of his professional practice only." It also follows from the express language of the act that such physician, dentist, or veterinary surgeon can prescribe such drugs when he "has been employed to prescribe for the particular patient receiving such drugs," and on whom he "shall personally attend in the course of his professional practice only," and such prescriptions must be made "in the legitimate practice of his profession," and then only when "employed to prescribe for the particular person receiving such drugs."

The above quotations from the law indicate the correct limitation on the professional prescription or distribution of said drugs by persons whether registered or not.

It is apparent from the foregoing that the duties of collectors and other internal revenue officers do not end, under the provisions of this act, with simple registration. If parties secure registration through misrepresentation or fraud, such registration is null and void and does not protect them from prosecution for the illegal use of these drugs, and it is the duty of collectors and other internal revenue officers when such cases are discovered to investigate the same, and where the law has been violated in line with the foregoing, to seize and proceed to forfeit the prohibited drugs illegally in possession of such parties, and recommend such persons to the district attorney for indictment and prosecution.

The foregoing has special application to those persons who, registering as physicians, prescribe or distribute narcotic drugs or preparations on receipt of mail orders received from so-called patients, or who, under the laws of the state or under municipal regulations, are not permitted to practice medicine.

Issuing Numbers

. . . In issuing registry numbers and special tax stamps under . . . Harrison Narcotic Law, collectors of interneal revenue will require persons making applications to state, under oath, in the blank space on Form 678, or if not sufficient space on the line for that purpose it should be in the form of an affidavit attached to the application on this form, that they will engage in administering, dispensing, or prescribing narcotic drugs only in the legitimate practice of medicine, dentistry, or veterinary surgery; or will engage in the business of producing, importing, manufacturing, compounding, dealing in, dispensing, selling, or distributing, as the case may be, only those narcotic drugs for which they are duly qualified by law, that is, "The undersigned is now engaged or on and after ————will engage in the legitimate practice of medicine (dentistry, or veterinary surgery), and is, or are, duly authorized by law to administer, dispense, or prescribe narcotic drugs," or "The undersigned is now engaged, or on and after ———— will engage in the lawful business of producing (importing, manufacturing, compounding, dealing in, dispensing, selling, or distributing) narcotic drugs."

FOREIGN

Plague Declining in Dutch East Indies.—According to the *Nederlandsch Tijdschrift*, the number of recorded cases of plague in Java during a recent eleven-day period was 119, with 103 deaths. During the corresponding period last year there were 694 cases, with 624 deaths.

Lectures on Medicolegal Aspects of Industrial Accidents.—The *Policlinico* mentions that Professor Bernacchi, consultant to the Cassa Nazionale infortuni sul lavoro, has been appointed lecturer at the University of Rome on industrial accidents. The official title of the course is "Unfortunistica medicolegale."

Antifly Campaign in Holland.—The Amsterdam Board of Health is busily distributing small illustrated pamphlets to educate the public in the dangers from the presence of flies and in means to exterminate them. The motto for the antifly campaign is repeated again and again; "No filth, no flies," *Waar geen vuil is, zijn geen vliegen.*

Italian Society for Experimental Phonetics.—An organization has recently been founded for this purpose, and one meeting has already been held at Rome. The membership includes physicians and scientists especially interested in the throat, and teachers of singing. Ferreri and Bilancioni reported the results of much research on fatigue of the larynx, and Gradenigo the results of study of phonation and respiration in a young woman with an entirely healthy throat who had been tracheotomized by mistake. Ponzo of Turin exhibited a modification of the Marey drum which records the tempo as well.

Metchnikoff's Seventieth Birthday.—Our foreign exchanges now contain an occasional article with the subheading, "Dedicated to Elias Metchnikoff on the Occasion of his Seventieth Birthday, May 16, 1915." These articles had been prepared for an international *Festschrift*, which was to have been presented to him on that date, but the war broke up the plans for the volume and the contributions are being published separately in various neutral journals. He is a native of southern Russia but has had a laboratory at the Paris Pasteur Institute since its erection, over twenty-seven years ago. His discoveries in phagocytosis were made previously in Italy. Although he studied under German physicians, he never took a degree in medicine.

Deaths in the Profession Abroad.—J. Englisch, professor emeritus of surgery, especially surgery of the urinary apparatus, at the University of Vienna, aged 80. The list of his works on urologic subjects is a long one.——M. Landau, assistant at the Freiburg Institute of Pathology, but lately in charge of a military hospital at Vienna, aged 29.——J. De Bary, of Frankfort-on-the-Main, aged 75.——Among those who have fallen on the battle field are A. Zahn, assistant at the university medical clinic at Greifswald, aged 29, son of the Geneva pathologist, F. W. Zahn; H. Deetjen, co-worker in the Institute for Cancer Research at Heidelberg since 1908, aged 48. It is to him we owe most of our knowledge of the blood platelets, as he worked out methods for isolating and keeping alive the platelets and studying their connection with coagulation.

WAR NOTES

Insane Among Crews of Interned Vessels.—Among the 5,000 sailors on the interned German vessels in New York harbor twelve cases of insanity have been reported to the county medical authorities in Hoboken. Health Officer Dr. Joseph Stack says that 90 per cent. of the interned crews suffer from anemia and are undernourished.

From Vienna.—A letter from Vienna in the *Medizinische Klinik* states that the limelight of public attention is now focused on the louse. The lay press teems with articles and advertisements on extermination of vermin. The newly organized society for prophylaxis of epidemic diseases is conducting a vigorous campaign for compulsory vaccination, which the medical profession has been urging for years. The authorities are now being besieged on all hands to order that the populace must be vaccinated. The medical faculty of the university bases its urgent plea mainly on the analogy between conditions in Austria now and those in Prussia after the war of 1870. In the army in both countries vaccination was compulsory, but the populace in general was not vaccinated, and Prussia then had an epidemic of smallpox, with over 240,000 cases. Compulsory vaccination was then enforced and by 1874 smallpox had been banished from the land. Recent Vienna statistics show that 98 per cent. of the mortality from smallpox is among the unvaccinated or never revaccinated.

LONDON LETTER

London, May 28, 1915.

The War

THE CONDITION OF SERBIA

From Valievo, in Serbia, typhus spread, being carried by soldiers returning to their homes and by travelers on the railway. In a few weeks the country had become a seething mass of misery and pestilence. The number of patients far exceeded the hospital accommodation. In the Nish hospital they lay three and four in a bed, while others lay on the floor and even under the beds. No medical service adequate to the conditions existed. Physicians and nurses and others bravely volunteered from Britain, France and America, and many of them succumbed to typhus. The work done by these devoted helpers is beyond all praise. One English woman, Mrs. Hardy, who came alone, took charge single-handed of a surgical hospital of about 500 patients, and with the help of one woman, a Serbian physician, turned it into a marvel of order and cleanliness. In February the British Army Medical Service sent out a sanitary department under Colonel Hunter. When they arrived they found that apart from the wounded there were 37,000 sick in the army, including 15,000 cases of fever, of which more than 8,000 were typhus and nearly 1,500 typhoid. It was difficult to ascertain precisely the condition of the civil population, but in Kraguievatz alone, a town of 20,000 inhabitants, there were 1,400 cases of typhus, and the number of deaths in three months had been 3,400, or thirty-four times the normal. By all indications, typhus and relapsing fever were increasing rapidly; there were rumors of plague, and an obvious danger of cholera, unless effective measures could be taken before the warm weather set in. To bring order and cleanliness into this chaos seemed beyond human powers. Colonel Hunter quickly grasped the fact that the first need was to break the lines of infection between the troops and the rest of the country. To effect this, three principal steps were taken. First, quarantine stations were established behind the lines; second, notice was given that all railway communication would be suspended for fifteen days; and third, all leave from the army was stopped, and all soldiers on leave were immediately recalled, so that there might be no danger of reinfecting the railway after the disinfection, which was to be carried out during the stoppage. The problem of typhus was comparatively simple, as that disease is spread by lice. Wholesale disinfection and cleansing were carried out. Wine barrels were fitted up as disinfectors and sent broadcast through the towns and villages. All the hospitals were thoroughly disinfected, and more beds and accommodation were provided as soon as possible. Notification of disease was enforced, and infectious patients were removed from their homes to hospitals, their houses being thoroughly cleansed, and their other inhabitants kept in isolation for fourteen days. Finally, it was laid down that no infectious patients should be discharged from hospital in less than four weeks. The sanitary staff went from place to place in a train specially fitted up with all necessary appliances, and containing sleeping accommodation for all on board. Inoculation was largely resorted to, especially against cholera, which always loomed ahead as the last and worst possibility when the other plagues were exhausted. As the British mission foresaw, the conditions became worse before they began to improve, but when they did, the change was rapid beyond expectation. April 5 there were 8,198 cases of typhus in hospital; April 18, only 948. In the same period relapsing fever had declined from 7,693 to 4,861, and typhoid from 1,443 to 1,126.

A Physician's Fear of Premature Cremation

The fear of premature burial, though not widespread, is well known, and a society for the prevention of this contingency exists. The will of a physician, Dr. A. W. Orwin, at one time physician to the Central London Throat, Nose and Ear Hospital, displays a similar fear with regard to cremation, and the precautions which he directed to be taken are most elaborate: that "until it was ascertained that he was in fact dead, his nose and mouth were not to be covered nor his body confined in any shell or coffin; that on his apparent death his body should be kept in a well-warmed bed for thirty-six hours and then placed in a warm room, with the windows partially opened, and watched for twelve days and nights or until definite signs of decomposition have set in. During this period, the tests given in a pamphlet by Sir Benjamin Ward Richardson, 'The Signs and Proof of Death,' were to be applied, and a bell was to be attached to his wrist. When decomposition should have set in, a surgeon was to sever completely the spinal cord high up in the body, which was then to be cremated."

BERLIN LETTER

Berlin, May 18, 1915.

Personal

Prof. Heinrich Fritsch died, May 14, at Hamburg, aged 71. He studied under Olshausen, took his medical degree at Halle, was called to Breslau in 1882 as director of the maternity, and in 1893 became professor of obstetrics at the University of Bonn and director of the university clinic for women. Among his various important contributions to obstetrics and gynecology are his studies of the displacements of the uterus and of the pathology of puerperal fever. His larger works include "Diseases of Women," "Obstetric Operations" and "Obstetrics from the Forensic Standpoint," some of which have passed through many editions. His last work was on "Therapeutic Technic in Gynecology" in the "Manual of Therapeutic Technic" published by Professor Schwalbe.

The medical faculty of the University of Heidelberg has awarded this year the Kussmaul medal and the money prize from the Kussmaul endowment to the surgeon, Professor Braun of Zwickau.

The War

VENEREAL DISEASES

As history has shown, there has always been a great increase in venereal diseases along with all wars, and it was evident to all that in the present war, also, the combating of venereal diseases would be one of the most important hygienic problems presented. Soon after the opening of the war, there was a lively discussion on the subject in medical literature. The national preventive organizations—in Germany the Deutsche Gesellschaft zur Bekämpfung der Geschlechtskrankheiten—were among the first to call attention to the immense import of the whole matter and to insist on enlightenment and warning and to urge energetic measures for protection and prophylaxis. When nine months of the war had passed, April 18, the board of the German Prophylactic Society held a meeting in which was discussed what has been accomplished to date and what is still to be done in the future. It was the general conclusion that the measures for enlightenment now in vogue on different sides must be vigorously continued. The distribution of enlightening circulars must be continued, especially the one issued by this society in an edition of two millions, and its other warning publications must be widely distributed. In addition to these, the short warning circular which has been published in an edition of 5,000,000 copies by the organized trade unions and other organizations of working men should be distributed. The latter circular was prepared at the instigation of the national insurance societies, and warns against the dangers of venereal diseases.

Of all measures, however, emphatic warning by word of mouth of the dangers of illicit intercourse was extolled as the most effectual. Particularly valuable for this is an outline prepared by Professor Uhlenhuth, consulting hygienist for the seventh army corps, to be used with a small atlas, for instructing the men when they are undergoing medical inspection. In the home zone, every new body of recruits should be instructed in the same way. In the barracks and hospitals, warning placards should be hung up; placards of this kind are supplied free of charge by the society. It was further emphasized as urgently necessary to enlighten the women in the home zone who would be exposed to danger, and to impress on them the necessity for seeking medical care at the first suspicion of infection. The proposal was also made to publish suitable articles from time to time in the trade and insurance journals, and that the Krankenkassen themselves should arrange for enlightening lectures and gatherings for talks on this subject for their insured members. It was further urged that the treatment of soldiers with venereal disease should be carried on in special wards. Each army corps should have a consulting venereologist—at least as an expert adviser for the consulting hygienist.

The most difficult phase of the problem is, of course, prostitution. As it is impossible to realize anything like complete sanitation of prostitution, an attempt should be made to detain under lock and key (*festhalten*), until peace is declared, the numerous Belgian and French prostitutes, if they cannot all be deported (*wenn man sie nicht abschieben kann*). Where this is not practicable, every measure for supervision should be applied under the control of German specialist physicians. The most important protecting means in the fight against prostitution are undoubtedly personal prophylactics. No prudery should be allowed to prevail here. Provision must be made to facilitate in every way the furnishing to the troops of prevention means; under all circumstances it must be required that after illicit intercourse a prophylactic protecting treatment must be applied. No soldier should be given a furlough without a previous medical examination, and furloughs should be refused to those with venereal disease. All these measures—so far as military conditions permit—must apply to the younger officers as well as to the men.

Of course these prophylactic and therapeutic measures should not be regarded as sufficient in themselves. Everything should be eliminated that increases the lure to extramatrimonial sexual intercourse. The German society proposes the following additional measures: (*a*) economic and social provision for the unemployed girls and women in the home zone and in the regions where the army is stationed; (*b*) the closest supervision of private quarters and their restriction to the utmost; (*c*) restriction of evening leave of absence; (*d*) restriction of alcohol, and an ample supply of nonalcoholic beverages; (*e*) exclusion of women from employment as waitresses in saloons or from admittance to them and similar places; (*f*) shortening of the hours saloons are allowed to be open; (*g*) provision of reading rooms, writing rooms and gathering places for the soldiers, and finally, (*h*) the prevention of quacks treating venereal diseases or advertising their services in any way.

A long discussion was devoted to ways and means to avert extensive spread of venereal diseases through the families after peace is declared. As experience has shown, toward the end of a war, when truce is declared, the venereal diseases become much more prevalent. All the authorities are convinced that when this time arrives all the prophylactic measures will have to be enforced with especial strictness. When peace is declared, all who have been treated for venereal disease during the war must be examined anew, and those still capable of infecting others should be retained in the region occupied by the army, in the reserve garrison, or at work otherwise, until they are cured. These measures should apply not only to the active soldiers but also to all other men connected with the army, railroad employees, postmen, bands of workmen, etc.

A number of the officials of the society declared it practically impossible to carry out still another measure suggested—although in itself extremely desirable—namely, that all those who have taken part in the war should be examined for gonorrhea and syphilis (including an examination of the blood) before they are dismissed to return home. Those who are not quite cured but no longer capable of infecting others should have opportunity for treatment offered them at once after their return home. The officials of the state insurance organizations have announced that they will provide means for the latter purpose on a large scale. The plan is to have dispensaries like those which have been doing good service at Hamburg since January, 1914, also organized by insurance officials.

The question was raised by the legal members of the board whether it would not conflict with professional secrecy to have the names of those still requiring treatment handed over to the insurance companies. This objection was met, however, by the provision in the German law on the subject, that it does not conflict with professional secrecy to pass the name from one official organization to another.

PARIS LETTER

Paris, May 27, 1915.

The War

FROZEN MEATS FOR THE ARMY

The provisioning of the army has considerably increased the consumption of butchers' meat. This increase amounts to about 400,000 tons per year or about 1,200,000 head of cattle. Our supplies of animals for slaughter are consequently being rapidly reduced and there is reason to fear that there will be insufficient production of meat animals for four or five years after the hostilities. As it is easy to see that the purchase of frozen meats is going to be continually more and more difficult, the Chamber of Deputies has just voted to authorize the minister of war to obtain for the use of the army annually 120,000 tons of refrigerated meat from our colonies or from foreign countries. The minister of war will be able to apply to the uses of the civil population all the meat which is not used for the troops. It is intended to buy frozen meats, which can better stand the delays and other hazards of transportation without risk of deterioration and which are better suited for the use of the army than meats which are simply refrigerated. There are facilities for cold storage in certain of our ports, amounting to 5,000 tons at Marseilles, 1,500 tons at Bordeaux, 4,000 at Havre; such facilities also exist in some of our other cities, as 5,000 tons at Paris, 2,000 at Dijon, 300 at Lyons and 250 at Nice. There are 800 refrigerating cars for use in transportation into the interior.

During the discussion of the bill, a deputy, M. Laurent Bougère, drew attention to the fact that, in the opinion of many physicians who have been at the front, the daily ration of 500 gm. of meat per man is excessive during the summer and ought to be partially replaced by vegetables. The ministers of agriculture replied that the meat ration has been reduced to 400 gm. for the troops of the second line but maintained at 500 gm. for those of the first line so that the average ration of the army is about 450 gm. Endeavors are being made to supply as large a quantity as possible of fresh vegetables at the front.

So far as refrigerated meats are concerned, it has sometimes happened that the cold storage houses have offered for consumption meats which were not all they should be. It is therefore of interest to know the precautions which the government has taken against this contingency. The director of the commissary at the war department has informed the budget commission that there are already and will be more facilities for the inspection of the sanitary condition of these meats, not only at the ports where they are landed and where they may be rejected if they are not altogether satisfactory, but also in the factories, where veterinaries are to have the right of examining the animals at the slaughter houses and also of inspecting the processes of manufacturing.

PREVENTION OF DECUBITUS IN TRAUMATISMS OF THE SPINAL CORD CAUSED BY WOUNDS OF WAR

At a recent session of the Académie de médecine, Dr. Pierre Marie, professor of pathologic anatomy at the Faculté de médecine de Paris, and Dr. Gustav Roussy, agrégé in the same subject at the same school, read an interesting paper on this topic. They believe that the long admitted theory that bedsores are the result of a trophic cutaneous trouble directly produced by the lesion of the nervous center is false. In reality the causes of decubitus consist of the following: (1) compression, indefinitely prolonged, of the projecting parts of the body, as the sacrum, heels or elbows, against the surfaces of the bed; (2) infection produced in the skin thus altered by prolonged and repeated contact with urine and feces. To prevent these lesions, these two causes must be eliminated. The position of these patients should therefore be changed every hour during the day and every two hours during the night. Also as soon as such wounded patients are soiled by their dejecta they should be immediately washed, powdered and placed on dry linen.

INDIRECT INTRA-OCULAR LESIONS BY FIREARMS

At the last session of the Académie de médecine, Dr. Lagrange, professor of clinical ophthalmology at the Faculté de médecine de Bordeaux, called attention to the fact that firearms may cause serious ocular lesions without touching the eyes. Bullets traversing the face or fragments of shell injuring the skull sometimes cause serious conditions in an eye apparently intact. Similar results may follow the displacement of the air caused by the explosion of a large projectile. In such cases there is a more or less accentuated laceration of the uveal tract. Such intra-ocular lesions resulting from concussion of the tissues or from simple displacement of the air make it possible to understand the existence of lesions of the nervous centers (spinal cord or brain) and of the peripheral nerves by projectiles which do not come into immediate contact with them or by the vibration of the air caused by the explosion of a large shell. The ophthalmoscope makes it possible to see in the ocular membranes lesions which are invisible in the nervous centers and trunks.

TREATMENT FOR TUBERCULOUS SOLDIERS

The Conseil général du département de la Seine-Inférieure has decided to found a departmental sanatorium for the treatment of soldiers who have contracted tuberculosis while serving under the flag.

Measures Against Alcoholism

The minister of justice has just addressed to the public prosecutors a circular with regard to the recent law forbidding the manufacture, the sale and the circulation of absinthe and similar liquors. He requests them to aid by all measures in their power in the campaign undertaken by the government against alcoholism by prosecuting all infractions of the law of Jan. 23, 1873, against drunkenness. This law provides punishment, not only for individuals found drunken in public places, but also for those who sell drinks to manifestly drunken customers or who serve alcoholic liquors to children under 16. The penalties are moderate for the first offense, but increase proportionately with repetition, reaching imprisonment for two months, prohibition of the consumption of drinks on the premises or even closing up the establishment. These penalties are so rarely applied that they have almost been forgotten. It is necessary that repeated offenders should be carefully distinguished and that all penalties called for by the nature of the case should be rigorously applied.

Jubilee of Professor Metchnikoff

A celebration which, owing to present circumstances, has taken on a personal character, was recently held at the Pasteur Institute; the occasion was the seventieth birthday anniversary of Prof. Elie Metchnikoff. Prof. Gaston Darboux and Dr. Roux reviewed the career and the works of the Russian scientist, the first on behalf of the Académie des sciences and the second on behalf of the Pasteur Institute. Professor Metchnikoff gave the audience an interesting talk on the prolongation of life.

Marriages

Fairfax Hall, M.D., New Rochelle, N. Y., to Miss Eleanor Reyburn Remy of Evanston, Ill., at Port Chester, N. Y., May 29.

Harvey Ward Van Allen, M.D., Springfield, Mass., to Miss Anna Marion Dostal, at Schenectady, N. Y., June 7.

Max J. Colton, health officer of Cumberland, Md., to Miss Florence E. Gibbs of East Orange, N. J., June 7.

Karl Miller Wilson, M.D., Baltimore, to Miss Mildred Hallowell Bentley of Sandy Springs, Md., June 1.

John A. Ascher, M.D., Sparks, Nev., to Miss Agnes C. McKinnon of Spokane, Wash., at Reno, June 2.

Cranford Haywood Douthirt, M.D., Roaring River, N. C., to Miss Lydia I. Reid of Towson, Md., June 2.

Walter M. Droll, M.D., Alta Vista, Kan., to Miss Hannah Amelia Netzig of Manhattan, Kan., May 26.

Todd J. Wilson, M.D., Negaunee, Mich., to Miss Lorena May Lockhart of Barrington, Ill., May 31.

Robert Marshall White, M.D., to Miss Mary Tivnan, both of Dorchester, Boston, June 1.

Maurice R. Perlstein, M.D., to Miss Rose Tratner, both of Chicago, June 2.

Deaths

Samuel Baldwin Ward, M.D. Georgetown University, Washington, D. C., 1864; assistant surgeon, United States Volunteers, during the Civil War; a Fellow of the American Medical Association; formerly president of the Medical Society of the State of New York and Albany County Medical Society; a member of the Association of American Physicians; once professor of anatomy and surgery in the Woman's Medical College of the New York Infirmary; for many years dean and professor of the theory and practice of medicine in Albany Medical College; attending physician to the Albany Hospital and consulting physician to the South End Dispensary; secretary and treasurer of the executive committee of the state normal college, Albany, and president of the board of trustees of the Dudley Observatory; died at his home in Albany, June 3, aged 73.

Frank Neall Robinson, M.D. University of Pennsylvania, Philadelphia, 1895; a Fellow of the American Medical Association; a member of the American Climatological Association and the National Association for the Study and Prevention of Tuberculosis; formerly of Camden, N. J., and a member of the city council for two terms; who went to California ten years ago on account of ill health and was for two years assistant superintendent of the Pottenger Sanatorium for Tuberculosis in Monrovia; died at his home in that place, May 25, aged 40.

John S. Mack, M.D. University of Pennsylvania, Philadelphia, 1892; a practitioner and druggist of Slatington, Pa.; assistant surgeon of the Fourth Pennsylvania Infantry, United States Volunteers, during the Spanish-American War, with service in Cuba; half owner of the Crescent Slate Company and its secretary and treasurer; committeeman, school director and treasurer of the school board for two years; a member of the borough council and in 1909, burgess; died in the Hotel McClodes, Buffalo, May 30, from heart disease, aged 45.

Spiro F. Sargentich, M.D. College of Physicians and Surgeons, San Francisco, 1902; formerly a Fellow of the American Medical Association, and a practitioner of Portland, Ore., and Tacoma, Wash.; but more recently a resident of Seattle; who went to Serbia a few months ago to assist in the fight against typhus fever in his native country; died recently from that disease, aged 41.

Gustavus Freedom Walker, M.D. Vermont Medical College, Rutland, 1888; of Boston; a veteran of the Civil War and surgeon-lieutenant of the Ancient and Honorable Artillery Company of Boston and medical director for the Massachusetts Department of the Grand Army of the Republic; died at his home in Boston, June 1, from cerebral hemorrhage, aged 71.

Walter J. Mitchell, M.D. Medical College of Ohio, Cincinnati, 1884; a member of the Indiana State Medical Association; formerly of North Vernon, Ind., and clerk of the Jennings County Circuit Court; died in Indianapolis, May 31, from the effects of poison self-administered, it is believed, with suicidal intent, while of unsound mind, aged 52.

Daniel R. McCormick, M.D. Jefferson Medical College, 1882; a Fellow of the American Medical Association; medical director of the Lancaster (Pa.) General Hospital; a member of the Lancaster school board and of the Board of Health of Lancaster County; died at his home in Lancaster, May 31, from cerebral hemorrhage, aged 58.

James Fulton McCutchan, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1868; a member of the Illinois State Medical Society and president of the Warren County Medical Society; a veteran of the Civil War, and one of the oldest practitioners of Warren County; died suddenly at his home in Alexis, Ill., May 28, aged 81.

Robert Clement French, M.D. Tulane University, New Orleans, 1906; of Natchez, Miss.; aged 35; a Fellow of the American Medical Association; a specialist on diseases of the eye, ear, nose and throat; oculist and aurist to the Natchez Hospital; died in the Touro Infirmary, New Orleans, May 30, after a surgical operation.

Harry H. Sherk, M.D. Jefferson Medical College, 1886; a Fellow of the American Medical Association; a member of the Camden (N. J.) Board of Health, and a practitioner and ophthalmologist of Camden for thirty-five years; died June 1, in a private hospital at Chestnut Hill, Pa., from cerebral hemorrhage, aged 55.

Herbert Lucian Grant, M.D. Tulane University, New Orleans, 1901; of El Campo, Texas; a member of the State Medical Association of Texas; died in the De George Hotel, Houston, Texas, June 2, from the effects of a gunshot wound of the head, self-inflicted, it is believed, with suicidal intent, aged 38.

James William Washington Culpepper, M.D. Chattanooga (Tenn.) Medical College, 1904; of Cullman, Ala.; a member of the Medical Association of the State of Alabama; aged 38; died in a hospital in Birmingham, Ala., May 27, from injuries sustained in an automobile accident two days before.

Morris Kush, M.D. Cornell University, New York City, 1913; an intern in Mount Sinai Hospital, New York City; aged 27; a member of the medical scholarship society of Alpha Omega Alpha; was accidentally drowned during a heavy windstorm, May 26, while canoeing on Lake George.

John Milton Shields, M.D. Albany (N. Y.) Medical College, 1868; formerly a Fellow of the American Medical Association; for many years a medical missionary of the Presbyterian Church in New Mexico; died at his home in Jemez Springs, N. M., May 23, aged 73.

Frank Eugene Baker, M.D. Long Island College Hospital, Brooklyn, 1891; formerly a practitioner of Florida, but more recently a resident of Woodford, Vt.; died at the home of his mother in North Adams, Mass., May 8, from acute prostatitis, aged 45.

Gustav Hahn, M.D. John A. Creighton Medical College, Omaha, 1903; a Fellow of the American Medical Association; a well-known practitioner of Omaha; died at his home in that city five weeks after an operation for cholelithiasis, aged 52.

Samuel Miner Glenn, M.D. Western Reserve University, Cleveland, 1910; formerly a Fellow of the American Medical Association; a member of the Ohio State Medical Association; died at his home in Warren, Ohio, May 30, aged 36.

Walter Carl Smiley, M.D. University of Southern California, Los Angeles, 1906; of Banning, Calif.; a Fellow of the American Medical Association; died at the home of his parents in Pasadena, Calif., May 30, from nephritis, aged 35.

T. Edwin Martin, M.D. Northwestern University Medical School, Chicago, 1904; a practitioner and druggist of Homedale, Ida.; formerly editor of the Homedale *Press*; died May 29, it is believed from an overdose of morphin, aged 32.

James M. Guess, M.D. Medical College of Georgia, Augusta, 1878; formerly of Centerville, Ga., but for several years a resident of Stone Mountain, Ga.; died in a hospital near Atlanta, May 26, from cerebral hemorrhage, aged 61.

Frederick Arthur Ruickoldt, M.D. University of Jena, Germany, 1865; a Fellow of the American Medical Association and founder of the New Haven Medical Association; died at his home in New Haven, Conn., June 2, aged 75.

John D. Miller, M.D. Louisville (Ky.) Medical College, 1903; of Batesville, Miss.; a member of the Mississippi State Medical Society; was instantly killed on Belmont levee by the overturning of his automobile, June 1, aged 36.

John A. Gale, M.D. Medical College of Indiana, Indianapolis, 1875; formerly of Denver, and local surgeon to the Colorado and Southern Railway; a resident of Los Angeles; died in Whittier, Calif., May 1.

William Wakeham, M.D. McGill University, Montreal, 1866; for thirty-six years fishery inspector for the lower St. Lawrence and gulf, and local justice of the peace; died at his home in Gaspé, Que., May 20, aged 70.

Samuel Cole, M.D. Rush Medical College, 1865; New York University, New York City, 1866; a Fellow of the American Medical Association; died at his home in Chicago, June 5, from heart disease, aged 70.

William Carey Allen, M.D. Hahnemann Medical College, Philadelphia, 1883; for twenty-seven years a practitioner of Colorado Springs, Colo.; died at his home in that city, June 2, from heart disease, aged 61.

Clayton M. Stewart, M.D. Missouri Medical College, St. Louis, 1857; Jefferson Medical College, 1860; for many years a practitioner of Scott County, Ill.; died at his home in Jacksonville, Ill., April 30, aged 83.

Edward Richard Johnstone, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1892; for several years a practitioner of San Luis Obispo County, Calif.; died at his home in Morro, Calif., May 20, aged 51.

Eliza J. Zimmerman Burnside, M D. Woman's Medical College of Pennsylvania, Philadelphia, 1860; for many years a practitioner of Philadelphia; died at the home of her sister in Tiffon, Ohio, May 28, aged 83.

Theodore F. Meisenheimer, M.D. New York University, New York City, 1880; a member of the Medical Society of the State of North Carolina; died at his home in Morven, May 27, aged about 63.

William Himmelsbach, M.D. Cooper Medical College, San Francisco, 1898; a member of the Medical Society of the State of California; of Watsonville, Calif.; died at Oakland, Calif., May 23, aged 52.

James Francis Hackett, M.D. State University of Iowa, College of Homeopathic Medicine, Iowa City, 1889; of Kellogg, Iowa; died at the home of his daughter in Maxwell, Iowa, May 9, aged 56.

Benjamin Frank Zerbe, M.D. Jefferson Medical College, 1878; formerly prothonotary of Lebanon County, Pa.; died at his home in Schaefferstown, Pa., about May 31, from acute meningitis, aged 61.

Addison Henry Dey, M.D. University of Pennsylvania, Philadelphia, 1881; for many years a practitioner of Trenton, N. J.; died at his home in that city, May 16, from cerebral hemorrhage, aged 58.

William Thomas Bogie, M.D. Bellevue Hospital Medical College, 1878; formerly a member of the Oklahoma State Medical Association; died at his home in Ardmore, Okla., May 29, aged 59.

George V. Hale, M.D. Jefferson Medical College, 1883; also a druggist; formerly local surgeon of the Southern Pacific System at Burbank, Calif.; died in Los Angeles, April 24, aged 61.

Louis Frederick Bischof, M.D. New York University, New York City, 1885; also a graduate of the New York College of Pharmacy; died at his home in New York City, May 23, aged 51.

Joseph S. Stanley (license, Mississippi), a Confederate veteran and a practitioner of Macon, Miss., for forty years; died suddenly in Valdosta, Ga., May 20, from heart disease, aged 68.

Robert Newton Fryer, M.D. University of Nashville, Tenn., 1870; for about sixty years a practitioner; died at his home in Newbern, Tenn., April 7, from senile debility, aged 85.

Charles Hiram Colegrove, M.D. Detroit Homeopathic Medical College, 1873; a veteran of the Civil War; died at his home in Willimantic, Conn., May 29, aged 73.

Daniel Joseph Mehegan, M.D. Harvard Medical School, 1894; a member of the Massachusetts Medical Society; died at his home in Taunton, Mass., April 21, aged 46.

J. Elizabeth Tompkins, M.D. Harvey Medical College, Chicago, 1896; for twenty-five years a practitioner; died at her home in Chicago, May 26, aged 70.

Francis Joseph Bicker, M.D. Jefferson Medical College, 1890; a practitioner and druggist of South Camden, N. J.; died at his home, May 24, aged 58.

William Ernest De La Perriere, M.D. Atlanta, Ga., College of Physicians and Surgeons, 1907; died at his home in Hoschton, Ga., May 22, aged 30.

John Franklin Marshall, M.D. New York University, New York City, 1890; died at his home in Brooklyn, May 31, from pneumonia, aged 50.

Henry Howard Townes, M.D. Medical College of Georgia, Augusta, 1896; of Poverty Hill, S. C.; died in Highlands, N. C., May 24, aged 45.

William Johnston DeWitt Sproule, M.D. University of Toronto, Ont., 1906; died at his home in Harlem, Mont., about May 20, aged 32.

Directus DeForest Cole, M.D. Hahnemann Medical College, Chicago, 1881; died at his home in Newark, N. Y., May 24, aged 60.

Eddie Wise Jenkins, M.D. Bellevue Hospital Medical College, 1883; of Farmdale, Fla.; died in Columbus, Ga., about May 21.

James A. Clementson, M.D. Hahnemann Medical College, Chicago, 1895; died at his home in Lancaster, Wis., May 19, aged 42.

Rufus N. Younger, M.D. University of Louisville, Ky., 1888; died at his home in Whitesboro, Tex., May 19, aged 61.

William A. T. Keeler, M.D. Jefferson Medical College, 1873; died at his home in Stroudsburg, Pa., May 24, aged 81.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

LOUISIANA GOES ON RECORD

What One Southern State Thinks of Fraudulent "Patent Medicines"

Readers of THE JOURNAL will remember that Dr. Oscar Dowling, president of the State Board of Health of Louisiana, and one of the Trustees of the American Medical Association, has been sued by the Chattanooga Medicine Company. The suit was based on the fact that Dr. Dowling, in his official capacity as State Health Officer, exhibited in the Louisiana "State Health Train," among other educational placards, one exposing Wine of Cardui. After the suit was brought, the State Board of Health of Louisiana officially upheld Dr. Dowling and also declared Wine of Cardui a fraud.

On June 14, the Louisiana General Assembly, in special session at Baton Rouge, passed the following, known as Senate Concurrent Resolution Number Six:

> "WHEREAS, Dr. Oscar Dowling, President of the Louisiana State Board of Health and, ex-officio, Commissioner of Food and Drugs, in his administration of these departments, has demonstrated the highest regard for his oath of office and courage in the case of public health against mercernary interests which have attacked the work of the Louisiana State Board of Health and discredited its efforts to protect the public; therefore be it
>
> "*Resolved,* By the Senate of the State of Louisiana, the House concurring, we approve the campaign of the Louisiana State Board of Health as conducted by Dr. Oscar Dowling, President, to rid the State of Louisiana of the pernicious patent nostrums so widely advertised and sold under misleading and fraudulent pretences as to curative properties.
>
> "*Resolved, further,* That we commend the action of the 'Louisiana Press Association' for its endorsement of the Louisiana State Board of Health in its effort to control the patent medicine evil, and Dr. Oscar Dowling, President, for his defense of the medical profession, the American Medical Association and the Louisiana State Board of Health at the Twenty-Sixth Annual Session of the Louisiana Press Association in Monroe, June 10, 1915, against the attack made by one of the speakers from a neighboring state who appeared on the program.
>
> "THOMAS C. BARRET, Lieutenant-Governor and President of the Senate;
>
> "L. E. THOMAS, Speaker of the House of Representatives;
>
> "L. E. HALL, Governor of the State of Louisiana."

It should be said that the Louisiana Press Association, which was recently in session at Monroe, La., had already gone on record against questionable advertising, especially as it refers to "patent medicines" and quackery. At its annual convention held last week this association reaffirmed its position on the question of fraudulent advertising and requested the president of the State Board of Health to furnish its members with a list of concerns that had been placed under ban by the board.

At the Louisiana Press Association's convention at Monroe a paper was read by one James A. Metcalf. This individual championed the cause of "patent medicines," by the usual method: vilifying the medical profession in general and the American Medical Association and the Editor of THE JOURNAL in particular.

This attempt on the part of the "patent medicine" interests to influence the press of Louisiana acted as a boomerang which was thus described by the Monroe (La.) *News-Star* in reporting the incident:

> ". . . the speaker failed utterly to help the cause of the patent medicine manufacturer with the Louisiana newspaper men who showed their feelings later by unanimously and loudly adopting a resolution endorsing the fight of the State Board on patent medicine frauds and requesting Dr. Dowling to furnish the press of the state a list of these nostrums so they may be banished from the advertising columns."

ARTICLE REFUSED RECOGNITION

Report of the Council on Pharmacy and Chemistry

Below appears an abstract of the Council's action on an article refused recognition which was not deemed of sufficient importance to require a lengthy report.

Iodex

Iodex is manufactured by Menley and James, Ltd., New York. It is advertised as

> ". . . an embodiment of vaporized iodin in an organic base, reduced and standardized at 5 per cent. by incorporation with a refined petroleum product."

The advertising conveys the impression that the effects of free iodin are to be obtained from the preparation; it is said to contain "5 per cent. Therapeutically Free Iodine," and to do

> ". . . everything the doctor expects of FREE iodin employed by inunction, without one physical or therapeutic drawback."

The statements are also made that the preparation "neither stains, irritates, blisters or cracks the skin," and that "thirty minutes after inunction iodin can be found in the urine."

The following report of an examination made by the Chemical Laboratory of the American Medical Association has been submitted to the Council:

> "Iodex is dark green, practically black. The green color is apparent when the ointment is rubbed on the skin, but disappears on continued rubbing. This nonstaining property is explained by the results of a test for free iodin, made on five specimens, four of which yielded only minute traces of free iodin, while the fifth yielded none. Of course, the statements that Iodex is an 'Effective Free Iodin Application Without Drawbacks' and also a means of 'Really Efficient External Iodine Therapy Without Stain or Irritation' contradict each other. Free iodin cannot be present in a sufficient quantity to be therapeutically efficient in any application which does not stain or irritate the skin.
>
> "The total iodin content of the five specimens was found to be 2.63 per cent.—a little over one-half of the content claimed.
>
> "Absorption and excretion experiments were performed to test the claim that 'thirty minutes after inunction iodin can be found in the urine.' In several subjects, from 1 to 2 gm. of Iodex was rubbed on the skin of the forearms, and the urine, for periods varying from seven to seventy-two hours, was collected and tested for iodin. In all of the tests the results were negative."

Iodex is advertised as beneficial in muscular soreness, sprains, sciatica, neuritis, chronic rheumatism, enlarged glands, orchitis, epididymitis, gout, burns and dermatomycoses. It is also said to be "Indicated in Glandular Enlargements, Inflammatory Conditions, Various Joint Diseases, Rheumatism, Skin Diseases, Chilblains, etc., etc."

To sum up:

1. As shown in the foregoing laboratory report, the composition is incorrectly stated, for the actual iodin content is only about half of that claimed.
2. *It is not true that the action of Iodex is essentially that of free iodin, which is the impression conveyed by the advertising.*
3. The assertion made in the advertising, that iodin may be found in the urine shortly after Iodex has been rubbed on the skin, has been experimentally disproved.

In view of these findings, the Council voted that Iodex be refused recognition for conflict with Rules 1, 4 and 6.

Modes of Infection in Tuberculosis.—Infection in tuberculosis results from close and perhaps prolonged association with some individual suffering from the disease. The nearness to the individual is not important, although droplet infection from forceful coughing is more apt to occur if contact is close; but the mere occupancy of a room previously used by a consumptive who has been careless in the disposal of his sputum is sufficient. Heat, poor ventilation and lack of sunlight increase the liability of infection, dust also acting deleteriously. Under ordinary conditions dishes are probably not responsible for the spread of the disease, but blankets and soiled or imperfectly cleaned linen may be an important source of infection.—Ernest A. Sweet, *Public Health Reports*, April 9, 1915.

Correspondence

Ben Franklin's Views

To the Editor:—The extract from the "Autobiography of Benjamin Franklin" (Miscellany, The Journal, June 5, 1915, p. 1933) gives a mistaken idea of the habits of our first American philosopher as regards his use of alcohol. Early in life as an impecunious printer's devil he may have been as abstemious as is asserted, but with the access of fortune and fame he certainly indulged more freely in "that muddling liquor" which he condemns. This is only an example of the not uncommon failing which he shared with less famous mortals in not always squaring his practice with his preaching.

Sir George Trevelyan, in his "American Revolution," says:

> "But Franklin was not long left without a colleague worthy of himself, and of the nation which he represented. The French treaty had been signed in February, 1778; and by the second week of April, John Adams was already supping with him 'on cheese and beer' in his suburban residence at Passy."

Fortunately the growing habit of abstinence from alcohol in the teachings of pathology and modern physiology rests on a surer foundation than is afforded in the precepts or practice of Poor Richard, whose homely and parsimonious maxims are today as archaic as the author's lightning rods or his old fur cap. Franklin's early objection to alcoholic beverages was chiefly on the ground of their expensiveness, and in an age of high cost of living and reckless expenditure this is a poor argument, which would apply with equal or greater force to the use of bottled spring water.

We are sufficiently grown up as a nation to hear with composure the truth about our early history, and it cannot harm the secure fame of Franklin to know that he was fond of both wine and women, a fact which he himself took no pains to conceal during his long and industrious lifetime. It is not recorded that his convivial habits or mulierosity ever impaired to the slightest degree his popularity or efficiency as a special ambassador to the gay court of Louis XVI during a dark and critical period of our country's history. In these stirring days of history in the making it is well to remember that not all of our Revolutionary heroes and patriots were impeccable saints, our school histories to the contrary notwithstanding. One of Franklin's bastard sons bore his name and was appointed a royal governor of New Jersey when that state was a crown colony. He was knighted by George III and remained a Tory partisan all his life.

Benjamin Franklin was a notorious sufferer from gout, and in his humorous dialogue under date of midnight, Oct. 22, 1780, occurs the following frank admission that he was far from being a total abstainer:

"*Franklin.* Eh! oh! eh! What have I done to merit these cruel sufferings?

"*Gout.* Many things: you have ate and drunk too freely and too much indulged those legs of yours in their indolence."

For physicians interested in the treatment of tuberculosis, it is of interest to recall that Franklin had knowledge of the value of fresh air methods equal to the most advanced views current today. He says:

> "It is recorded of Methuselah, who, being the longest liver, may be supposed to have best preserved his health, that he slept always in the open air; for when he had lived five hundred years an angel said to him: 'Arise, Methusaleh, and build thee an house, for thou shalt live yet five hundred years longer.' But Methuselah answered and said: 'If I am to live but five hundred years longer, it is not worth while to build me an house; I will sleep in the air, as I have been used to do.' Physicians, after having for ages contended that the sick should not be indulged with fresh air, have at length discovered that it may do them good. It is therefore to be hoped that they may in time discover likewise that it is not harmful to those who are in health, and that we may then be cured of the aerophobia that at present distresses weak minds, and makes them choose to be stifled and

poisoned rather than leave open the window of a bedchamber or put down the glass of a coach."

John Adams, who attained the venerable age of 91, was never converted by the doctrine of his eminent colleague whom he long survived, and he was always convinced that Franklin, who died at the age of 84, was prematurely cut off by his foolish habit of exposing himself to drafts of air.

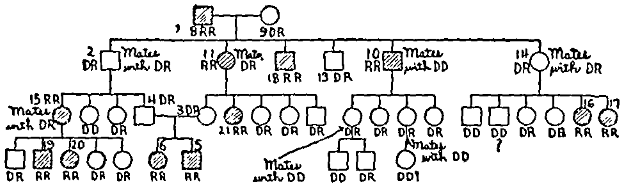
Henry L. Shively, M.D., New York.

Polydactylism as a Hereditary Character

To the Editor:—I have been vastly amused but not convinced by the easy grace with which Dr. W. R. Tymms (The Journal, June 5, 1915, p. 1931) surmounts the difficulties which I imagined I encountered in proving polydactylism a recessive hereditary character.

In the first place, as regards the question of an imperfect dominance of either the normal or the polydactyl condition, allow me to point out that such a conclusion was reached some time since by Bateson and Castle, whose names *are most intimately connected with experimentation to determine* the facts of mendelian heredity, although they seem to feel that the *polydactyl* condition is the imperfect dominant.

It will be recalled that as an instance which might tend to prove polydactylism a recessive character, I suggested that 4 and 3, being offspring of polydactylous progenitors, could each very well be considered DR in composition and they, each contributing an R to 5 and 6, cause this pair to be RR and thus to present the recessive polydactyl character (referring to my chart as edited by Dr. Tymms), all other polydactylous members of the tree exhibiting the character because of the imperfect dominance of the normal five-fingered state. Now Dr. Tymms labels 8 as RR, which means that *both* of his parents must have borne this factor. Then 8 marries a woman 9 labeled, by him, as DR, meaning that she too bears the same polydactylous factor. And, as if there were some controlling destiny operative, 2, 11, 14 and 15 all *meet and mate with a DR each.*



Squares indicate males, circles, females. Shaded areas indicate affected persons (polydactyls).

If polydactylism is carried as a potential factor so generally, I submit that we must soon become a polydactylous race. Otherwise, it would appear that when a hurdle is encountered, the easiest way of getting by is simply to remove it.

Julian W. Brandeis, M.D., New York.

The Country Doctor

To the Editor:—It seems to me that both Dr. Flancher and Dr. Ames (The Journal, March 27, 1915, p. 1095; June 5, 1915, p. 1931) have missed the mark. The first requisite of either a country or a city physician is character; then comes ability. I will take off my hat to the physician who says he does not know, but who at the same time will work to find out. There is no question that the city physician who realizes his responsibilities can do better work with less effort than the country physician. Every man should realize his limitations. We all have them. Then he should not hesitate to call a better man, even if he is a city man. Thwarted ambitions act like poison in human nature, and a normal and temperate satisfaction of ambition is what keeps it sweet and sane. The clinics and hospitals in the city give an opportunity which we country fellows hunger for. We cannot all live in the city. Patients in the country are entitled to as good treatment as can be obtained anywhere. If we cannot give it, we should call in the man who can, no matter where he lives.

Henry C. Caldwell, M.D., St. Croix Falls, Wis.

The Tendency to Write Long Sentences

To the Editor:—I desire to call attention to what seems to be a growing evil in the matter of literary productions by physicians and others, although not a new one. It is a tendency to make long sentences which often require to be read two or three times before the meaning can be ascertained, consuming needlessly the time of the reader. In the last number of one American medical journal, for example, is an otherwise admirable paper in which this is the case. I experienced this in reading the paper, so that it took me twice as long to read it as it should have done.

An editorial reference to this tendency I think would be helpful to the reader, and do the author no harm. As I have said, this practice is not limited to the medical writer, but it is with him that we doctors are for the most part concerned.

James Tyson, M.D., Philadelphia.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THE KRISTELLER TECHNIC

To the Editor:—In Dr. Baer's article on "Scopolamin-Morphin Treatment in Labor" (The Journal, May 22, 1915, p. 1723), under Case 9, he says: "Patient was delivered by Kristeller." What is Kristeller? I have searched all my obstetric literature and can find nothing.

J. M. Heyde, M.D., Loudonville, Ohio.

Answer.—The Kristeller technic is a method of expression of the fetus suitable for those cases in which labor is not progressing satisfactorily and in which an outlet forceps or more recently a dose of pituitary extract is usually employed.

The head should be in the vulva, and the abdomen must be thin and relaxed enough to permit the obstetrician's assistant to grasp the fundus efficiently. A light anesthesia may be used to facilitate this hold. The grip is on the fundus, the fingers of the two hands parallel behind and the thumbs in front. The expression should be carried out in one or two sustained efforts, preferably during a uterine contraction. The line of force should be exerted in the direction of the axis of the inlet, if necessary shifting the uterus to meet this requirement.

This method should not be undertaken unless the obstetrician feels assured of success. Such force, if applied at the placental site and unsuccessful, might result in premature detachment and death of the fetus. The uterus might likewise be seriously injured. If there is reason to suspect inflammatory involvement of the adnexa, the procedure should not be considered. The following is a reference to the original article of Kristeller: "Die Expressio Foetus; Neues Entbindungsverfahren unter Anwendung äusserer Handgriffe," *Monatschr. f. Geburtsh. u. Frauenkr.*, 1867, xxix, 337.

OUR NEUTRALITY QUESTIONED

To the Editor:—I was much amused at your neutrality being questioned because the letter "G" follows "F," when Dr. Heisen queried why the letter from your correspondent in Germany is placed to follow the letter from your correspondent in France, and he accused you of favoritism. (The Journal published Dr. Heisen's letter May 29, in Knocks and Boosts Department, page 22.)

I have noticed the tendency in The Journal to arrange all sequences alphabetically. In the Current Literature Department, in particular, I can always find, in their respective alphabetical positions, the domestic journals and the journals from England, from France, from Germany and Italy, with the Scandinavian journals always last. The alphabetical arrangement saves much time and labor in looking up things, but one discrepancy I have always wondered at, namely, that the Brazil and Argentine journals follow Italy.

A. M. J.

Answer.—*In case of the journals in foreign tongues, it has* been found more convenient for both readers and translators to arrange them by the languages—grouping the allied ones—rather than by the names of the countries. This makes no difference in the sequence English, French, German and Italian, but Brazil journals are in Portuguese and the Argentine in Spanish. With the Swedish are grouped the Danish and Norwegian. Persons who can read one of the languages in these groups usually can read all the others in the group.

THE HARRISON NARCOTIC LAW

To the Editor:—A habitué uses, on an average, 3 ounces of laudanum a week I write a prescription for this amount each week for him. Is it illegal for me to write "Sig.: Laudanum—Poison" as directions for the druggist to write on bottle, or should the directions be for a reduction of the dose on each prescription written for a habitué, regardless of the quantity the prescription calls for to comply with the Harrison law?

J. S. G.

Answer.—Treasury decision 2200, issued May 11, directs that where a physician, dentist or veterinarian prescribes any of the drugs covered by the law, in a quantity more than is apparently necessary to meet the immediate needs of a patient in the ordinary case, or where it is for the treatment of an addict or habitué to effect a cure, or for a patient suffering from an incurable or chronic disease, such physician, dentist or veterinary surgeon should indicate on the prescription the purpose for which the unusual quantity of drugs so prescribed is to be used. In cases of treatment of addicts, these prescriptions should show the good faith of the physician in the legitimate practice of his profession by a decreasing dosage or reduction of the quantity prescribed from time to time, while, on the other hand, in cases of chronic or incurable diseases, such prescriptions might show an increasing dosage or increasing quantity. In accordance with this ruling, prescriptions given to addicts should show a definite dosage decreasing from time to time.

LITERATURE ON PROSTATITIS

To the Editor:—Please publish a list of literature on acute and chronic prostatitis.

C. W. Davidson, M.D., Madisonville, La.

Answer.—The following is a list of articles on this subject:

Smith, E. O.: Pathology of the Prostate, The Journal, Dec. 6, 1913, p. 2035.
Young, H. H.: Rôle of Prostate and Seminal Vesicles in General Toxemias, The Journal, Sept. 13, 1913, p. 822.
McCrae, Thomas: Remote Effects of Lesions of Prostate and Deep Urethra, The Journal, Aug. 16, 1913, p. 477.

Rollier, A.: La Cure de Soleil, Lausanne, Constant Tarin, 1914, cloth, pp. 217, with 147 illustrations, price, 20 francs.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, July 6. Chairman, Dr. W. H. Sanders, Montgomery.
Alaska: Juneau, July 6. Sec., Dr. Harry C. DeVighne, Juneau.
Arizona: Phoenix, July 6-7. Sec., Dr. John Wix Thomas, Phoenix.
Colorado: Denver, July 6. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.
Connecticut: New Haven, July 13. Sec., Dr. Charles A. Tuttle, 196 York St., New Haven; Eclectic: New Haven, July 13. Sec., Dr. T. S. Hodge, 19 Main St., Torrington; Homeopathic: New Haven, July 13. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.
District of Columbia: Washington, July 13. Sec., Dr. Edgar P. Copeland, The Rockingham, Washington.
Illinois: Chicago, June 24-26. Sec., Dr. C. St. Clair Drake, Springfield.
Indiana: Indianapolis, July 13-15. Sec., Dr. W. T. Gott, 120 State House, Indianapolis.
Maine: Augusta, July 6-7. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.
Maryland: Baltimore, June 21. Sec., Dr. J. McP. Scott, Hagerstown.
Massachusetts: Boston, July 13-15. Sec., Dr. Walter P. Bowers, Room 501, No. 1 Beacon St., Boston.
Missouri: St. Louis, June 21-23. Sec., Dr. J. A. B. Adcock, State House, Jefferson City.
New Hampshire: Concord, July 6-7. Regent, Mr. H. C. Morrison, Concord.
New Jersey: Trenton, June 22-23. Sec., Dr. H. G. Norton, 429 E. State St., Trenton.
New Mexico: Santa Fe, July 12. Sec., Dr. W. E. Kaser, East Las Vegas.
New York: Albany, Buffalo, New York and Syracuse, June 29-July 2. Mr. Harlan H. Horner, Chief, Examination Division, State Education Bldg., Albany.
North Dakota: Grand Forks, July 6-9. Sec., Dr. G. M. Williamson, Grand Forks.
Oklahoma: Oklahoma City, July 13. Sec., Dr. Ralph B. Smith, 502 Daniel Bldg., Tulsa.
Oregon: Portland, July 5. Sec., Dr. L. H. Hamilton, Medical Bldg., Portland.
Rhode Island: Providence, July 1. Sec., Dr. Gardner T. Swarts, State House, Providence.
South Dakota: Pierre, July 12. Sec., Dr. Park B. Jenkins, Waubay.
Tennessee: Memphis and Nashville, June 25, 26. Sec., Dr. A. B. De Loach, 426 Scimitar Bldg., Memphis.
Texas: Austin, June 22-24. Sec., Dr. M. P. McElhannon, Belton.
Utah: Salt Lake City, July 5. Sec., Dr. G. F. Harding, 407 Templeton Bldg., Salt Lake City.
Vermont: Burlington, July 1-3. Sec., Dr. W. Scott Nay, Underhill.
Virginia: Richmond, June 22-25. Sec., Dr. J. N. Barney, Fredericksburg.
Washington: Seattle, July 6. Sec., Dr. G. N. Suttner, Baker Bldg., Walla Walla.
Wisconsin: Milwaukee, June 29-30—July 1. Sec., Dr. J. M. Beffel, 3200 Clybourn St., Milwaukee.
Wyoming: Laramie, June 28-30. Sec., Dr. H. E. McCollum, Laramie.

Important Changes in the New Jersey Medical Practice Act

The following abstract from the New Jersey state medical law, as recently amended, has been received from Dr. H. G. Norton, secretary of the New Jersey State Board of Medical Examiners:

A. From and after the first day of July, 1919, no person shall be admitted to examination for license to practice medicine or surgery, unless he shall present to said board a certificate from the Commissioner of Education of this state, showing that in addition to, and subsequent to, obtaining the preliminary and academic education above mentioned, i. e., an academic education consisting of a four year's course of study in an approved public or private high school, or the equivalent thereof, and prior to commencing his or her study in a medical college, he or she has completed a satisfactory course of one year in a college or school of art and science approved by the Commissioner of Education of this state, during which year he or she has studied either French or German, and also chemistry, physics and biology.

B. From and after the first day of July, 1920, no person shall be admitted to examination for license to practice medicine or surgery, unless he shall present to said board a certificate from the Commissioner of Education of this state, showing that in addition to, and subsequent to, obtaining the preliminary and academic education mentioned in the first paragraph of this section and prior to commencing his or her study in a medical college he or she has completed a satisfactory course of two years in a college or school of art and science approved by the Commissioner of Education of this state, during which two years he or she has studied either French or German; and also chemistry, physics and biology.

C. Every applicant for admission to examination for a license to practice medicine or surgery shall, in addition to the above requirements, prove to said board that he has received a diploma conferring the degree of doctor of medicine from some legally incorporated medical college of the United States, which college, in the opinion of said board, was in good standing at the time of the issuance of said diploma.

After the first day of July, 1916, such applicant shall, in addition to the above requirements, further prove to said board that after receiving such degree, diploma or license; he has served as an intern for at least one year in a hospital approved by said board.

This board will not consider a course of lectures in which the applicant has been conditioned in more than one subject satisfactory, unless these conditions shall have been passed off before entering a subsequent course. If the student be conditioned in a number of subjects sufficient to prevent him advancing to a higher grade in the same college, that year will not be considered as one of the four courses required by this board, even though at another college he be allowed to enter an advanced class; but he must take that entire year over, whether at the college where he failed or at another one.

Connecticut March Report

Dr. Charles A. Tuttle, secretary of the Connecticut Medical Examining Board, reports the practical and written examination held at New Haven, March 8-9, 1915. The total number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 12, of whom 8 passed and 4 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Rush Medical College	(1906)	82.4
Harvard University	(1903)	75.3
Dartmouth Medical School	(1911)	80.1
Albany Medical College	(1914)	77.3
Coll. Phys. and Surgs. in City of N. Y.	(1887) 76.4; (1903)	81.6
Columbia University	(1912) 85.5; (1914)	79.4
FAILED		
College of Phys. and Surgs., Boston	(1908)	61.3
College of Phys. and Surgs., in the City of N. Y.	(1907)	66.7
Medico-Chirurgical College of Philadelphia	(1914)	71.2
Royal University of Naples	(1912)	45.2

Utah April Report

Dr. G. F. Harding, secretary of the Utah State Board of Medical Examiners, reports the written examination held at Salt Lake City, April 5-6, 1915. The total number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 7, of whom 6 passed and 1 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Pacific Medical College*	(1914)	78.3, 79
John A. Creighton Medical College	(1914)	81.5, 82.1
Western Reserve University	(1912) 84.7; (1913)	80.4
FAILED		
Michigan College of Med. and Surg.	(1904)†	

* This institution is located at Los Angeles, and grants as much as three years of advanced standing for work done in osteopathic colleges, and is, therefore, classified among such institutions.

† No grade given.

Iowa May Report

Dr. Guilford H. Sumner, secretary of the Iowa State Board of Medical Examiners, reports that 2 candidates were licensed on examination and 8 through reciprocity, May 6, 1915. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Hahnemann Medical College and Hospital, Chicago	(1909)	83
Rush Medical College	(1885)	75.9

College	Year Grad.	Reciprocity with
LICENSED THROUGH RECIPROCITY		
Northwestern University	(1911)	Missouri
Rush Medical College	(1906)	Missouri
Barnes Medical College	(1902)	Missouri
St. Louis College of Physicians and Surgeons	(1895)	Missouri
Washington University	(1912)	Missouri
John A. Creighton Medical College	(1913)	Nebraska
University of Nebraska	(1909)	Nebraska
Wisconsin College of Physicians and Surgeons	(1912)	Missouri

Book Notices

Die Chirurgischen Indikationen in der Nervenheilkunde. Ein Kurzer Wegweiser für Nervenärzte und Chirurgen. Von Dr. Siegmund Auerbach, Vorstand der Poliklinik für Nervenkranke in Frankfurt a.M. Paper. 6.40 marks. Pp. 204, with 20 illustrations. Berlin: Julius Springer, 1914.

The author believes that every neurologist should be able to determine and should determine the cases involving the nervous system in which operation should be performed by the surgeon, but he does not approve of the neurologist as a rule being at the same time the operator. The two fields he holds to be quite separate and distinct. The subjects first discussed are exophthalmic goiter and tetany. Three forms of exophthalmic goiter are described, one in which the thyroid is chiefly at fault, one in which both the thyroid and thymus are involved, and a third in which the thymus is the chief organ at fault. In the latter variety the thyroid is only quantitatively involved, but as it is at times difficult to recognize these different forms, he considers it one's duty to remove the thymus as well as to operate on the thyroid in all severe cases of exophthalmic goiter. In severe cases of tetany, transplantation of parathyroids should be tried after the method of von Eiselsberg. The question of the operative treatment of epilepsy is discussed pro and con at considerable length without much headway being made, although the author is inclined to believe that operations should be done more frequently to relieve the slight leptomeningitis with serous effusion, which he thinks is often the cause of epilepsy. In hydrocephalus, lumbar puncture repeated at regular intervals is strongly recommended when the canals are not closed above, and tapping the ventricles and puncturing through the corpus callosum in other cases. The operative treatment of head injuries, tumors of the brain, and the various forms of neuralgia is thoroughly covered. The work closes with quite an extensive bibliography.

A Nursing Manual for Nurses and Nursing Orderlies. By Duncan C. L. Fitzwilliams, M.D., Ch.M., F.R.C.S., Surgeon in Charge of Outpatients, St. Mary's Hospital. Cloth. Price, $2. Pp. 466, with illustrations. New York: Oxford University Press, 1914.

This book, the author hopes, will "increase medical knowledge among nurses, orderlies and Red Cross workers." As much of the first aid work falls to the share of the male nurses and orderlies, first aid in the field has been very fully dealt with, especially the various form of bandages, moving and lifting the injured singlehanded and with help, carrying by stretcher, improvising stretchers, loading and unloading the wounded, and artificial respiration. Except for these special subjects, the work differs little from other books on nursing.

Care and Feeding of the Infant. Practical Advice for Mothers and Nurses. By George D. Lyman, A.B., M.D., with an *Introduction by* Ray Lyman Wilbur, M.D., Dean of College of Medicine, Leland Stanford Jr. University. Cloth. Price, $1 net. Pp. 132. San Francisco: Paul Elder & Co., 1915.

This book is sound in principle, and the suggestions and advice are sensible and practical. The subjects concern rules for mothers during the prenatal period, the examination of the new-born infant, physical and mental development, the care of the new-born infant, infant feeding, the most frequent diseases of infancy, the training of the child, special directions for enemas, poultices, packs, etc., and a final chapter of modern formulas for the infant. The book is one which may be recommended to prospective mothers.

Mothercraft. By Sarah Comstock. Cloth. Price, $1. Pp. 214. New York: Hearst's International Library Company, 1915.

The articles making up this book appeared as a serial in *Good Housekeeping Magazine*. The author prefaces her work with an acknowledgment to numerous authorities whose names are listed. The book is one which can be recommended to a prospective mother. It is entertainingly written and well illustrated, and the scientific statements are shouldered by the authorities from whom the author has so casually borrowed.

Medicolegal

Liability of Carrier Wrongfully Taking Away Injured Passenger

(Easler vs. Columbia Railway, Gas & Electric Co. (S. C.), 84 S. E. R. 417)

The Supreme Court of South Carolina affirms a judgment for $1,000 damages in favor of the plaintiff, a boy who, while a passenger on one of the defendant's cars and preparing to alight, was thrown to the ground and had his shoulder bones injured. The court says that the boy's mother, living hard by, came out to the scene, and, it was alleged, desired to take the boy into her house, but the conductor carried the boy to the end of the line and back into the city to the company's surgeon for treatment, as he was bound to do by the company's rules. He was treated by the surgeon and discharged for well. The defendant asked that the jury be instructed that there was no evidence in the case that would warrant them in giving any verdict on account of alleged negligent treatment on the part of the physicians employed by the defendant. It is true that if a carrier shall (1) employ a surgeon to treat a patient, (2) and if the surgeon be reasonably competent, (3) and if the service to the patient be gratuitous, and (4) if the surgeon neglect the patient, then the master is not liable for the ill consequences to the pâtient. In that case, if the carrier owed any duty, he performed it when he selected a reasonably competent surgeon. In that case the carrier, as the alleged master of the surgeon, is not held liable for maltreatment, and on the theory that he has no power to direct the surgeon about his work. But in this case there was testimony—denied by the defendant, it was true—that the boy was taken away from the mother against her consent. If that was true, and of it the jury judged, then there was evidence which warranted the jury in giving a verdict on account of the treatment of the physicians, using the language of the requested instruction. It may be the duty of the carrier to call a surgeon to serve an injured passenger in a sudden emergency; but it is not the duty of the carrier to do so when the natural guardian of the injured passenger is present and dissents. It is manifest that the defendant had no right to the custody of the boy against the mother's consent; the forcible taking of custody was in itself a wrong; the relation of carrier and passenger was not immediately terminated; and, if the boy was injured while thus in the defendant's custody, no matter if by a surgeon, then the company was liable for such injury. The carrier would not be allowed to deny that it inflicted the injury.

Insured Having Tumor of the Pituitary Body

(Van Woert et al. vs. Modern Woodmen of America (N. D.), 151 N. W. R. 224)

The Supreme Court of North Dakota affirms a judgment for the defendant, which was sued on a benefit certificate or policy of fraternal life insurance issued to the plaintiff's husband on an application made May 8, 1909. The court says that the undisputed testimony showed that in the year 1907 the insured's left eye became inflamed, presumably from flax chaff. On bandaging the eye, he discovered that he could not see well with his right eye. His condition growing no better, in the spring of 1908 he consulted a physician relative to his eyes, and the physician found that there existed a partial atrophy of the optic nerve, slight as to the left eye, and more pronounced as to the right eye. Later, the insured consulted specialists, and in the early summer of 1910 he was operated on for tumor of the pituitary body. He died about Aug. 31, 1911, the direct cause of his death being the tumor of the pituitary body. The expert on neural surgery who performed the operation mentioned testified that in his opinion the insured had been suffering from the tumor of the pituitary body for many years, and that it was in existence as early as 1907. The principal defense was that the policy was void because the answers made by the insured in his application, to the effect that he never had a tumor, and that he had not within the last seven years been treated by or consulted any person, physician or physicians in regard to his personal ailments were untrue, and that his untrue answers to such questions were breaches of the warranties contained in the application and beneficiary certificate. The court is of the opinion that, even though the applicant believed that the trouble with his eyes was only local, still the defendant had a right to a complete, truthful answer in order that it might make such further investigation as it deemed necessary. The applicant warranted that he had not consulted a physician within the last seven years, and that he was not suffering with a tumor. The undisputed evidence showed that both of these warranties were untrue. They were both material facts which increased the risk. The truth of the conditions warranted was a condition precedent to a recovery on the policy. Whether or not the applicant acted in good faith was immaterial.

Liability for Wrongful Detention of Patient in Hospital

(Cook vs. Highland Hospital et al. (N. C.), 84 S. E. R. 352)

The Supreme Court of North Carolina affirms a judgment, amount not stated, in favor of the plaintiff, who sued the hospital and its medical director for damages for alleged unlawful detention, etc. The court says that the defendants denied that any wrongful acts were committed by them, and contended that they had a right to do what was done because the plaintiff signed an agreement on her entrance that she would be subject to the rules and regulations of the institution, and that she could not be set at liberty without danger to herself. But the trial judge properly told the jury that the plaintiff could not thus surrender control of herself to another by signing a paper at her entrance into the institution. "Good faith" is not a defense to the recovery of compensatory damages when the jury finds that there was illegal restraint of liberty and compulsory massage and hypodermic injections and other physical treatment on a defenseless woman, who was in the absolute power of the defendants and kept immured under lock and key and with barred windows, without information given by them to her family of her condition, and she denied all communication with them.

The plaintiff was not committed as insane, and, if she had been, the defendants did not account for the fact that they accepted her as sane by signing the agreement with her on her entrance into the institution. If she subsequently became insane, it was the duty of the institution to have at once notified her mother and sister. The testimony of the defendants, however, was that she was not insane. Evidently the medical director believed that he had absolute control of the plaintiff and the right to imprison her if she opposed his orders or will, and the right to impose on her whatever treatment he thought best, and that the family need not be consulted any more than the plaintiff herself. The effect of being at the head of such an institution is very often—too often—to render the person in charge callous and autocratic, and in his own opinion irresponsible to any one.

In this land, the law guarantees liberty to every one, subject to restraint only in the modes provided by the law; and even then there is the right to review the conduct of those in charge of those deprived of their liberty. The plaintiff was not committed to the care of the defendants by any legal proceedings adjudging her insane, and her signing the paper agreeing to the rules and regulations of the institution was not irrevocable. It did not subject her to the irresponsible power and control of the defendants. If the plaintiff did not abide by her agreement to obey the rules and regulations of the institution, the remedy of the defendants was to discharge her or, if her condition forbade this, to notify her relatives, and not to imprison her and force her to do their will.

Instructions are approved, which told the jury, among other things, that, even though she went in under the paper above referred to, if she was found perfectly rational, and knew what she was doing—what she wanted and did not want—and she wanted to leave the institution, and expressed it to the hospital authorities, and they knew of that fact, and then after that restrained her of her liberty, then it would be in law a wrongful detention, unless they were justified in restraining her under those rules of humanity and regard for her welfare which would permit her to be detained and restrained until reasonable apprehension of doing herself bodily harm had passed, if she was so nervous from any ailment or disease and so irrational that there was reasonable probability that, if released at the time, she would do herself some bodily harm.

Chronic Duodenal Ulcer

Dr. William J. Mayo, Rochester, Minn.: Published in The Journal, this issue, p. 2036.

Medical Cure of Gastric and Duodenal Ulcer by Means of Efficient Removal of Gastric Juice Corrosion

Dr. B. W. Sippy, Chicago: Published in The Journal, May 15, 1915, p. 1625.

DISCUSSION

Dr. L. F. Barker, Baltimore: Differences still remain between physicians and surgeons both as to diagnosis and to therapy. The diagnosis of duodenal ulcer is easy in typical cases and no one need mistake them. But medical men see so many cases of so-called hyperchlorhydria of a different type, that although Moynihan says these cases are all cases of ulcer, medical men are and will continue to be skeptical about it. In the doubtful cases we do find a real help in roentgenography and particularly in serial roentgenography. From chronic cholecystitis, chronic pancreatitis and chronic appendicitis the differentiation of duodenal ulcer is very difficult at times, and the findings at operation are often very disappointing. As to therapy, the question still is open. When there is hemorrhage, obstruction or perforation, surgery is, of course, our only proper recourse. But in milder cases we are in doubt; the gastrologists tell us that they see many recoveries under medical management. There may be some significance in the fact that more recent graduates in medicine suffering with this condition tend to be operated on, while the older men tend to prefer the medical treatment. Medical men and surgeons must continue to work together on this problem until the interchange of opinion and experience shall bring us at length to a conclusion.

Dr. William H. Welch, Baltimore: As to the preponderance of duodenal over gastric ulcer, Dr. Mayo has made out his case — at least *for those cases coming under observation.* But these observations do not determine the percentage of incidence in all classes of cases. This is not the last word on this question of comparative incidence.

Dr. Frank Billings, Chicago: Rosenow's work on the relation between infectious foci and ulcer, both of stomach and duodenum, will certainly receive more consideration in the etiology of these conditions than heretofore, and will be found to have a bearing on the nonhealing of ulcers. Moreover, it will be accepted that failure to treat infectious foci will invite recurrences of ulcer. Spasm and hypertrophy of muscle, together with infiltration of tissues as a contributing cause, may produce obstruction; this must be admitted; because from ulcers so situated that these factors cannot cause obstruction no such severe symptoms arise and thus no diagnosis is made except of hyperacidity. In watching Dr. Sippy's work, I have too often seen obstructive symptoms disappear to doubt that they can both originate in the way indicated and that they can be dissipated with the healing of the ulcer under medical management.

Dr. A. McPhedran, Toronto: I would like to ask Dr. Mayo if it is not true that after gastro-enterostomy the gastric peristalsis is still toward the pylorus, and are not the duodenal tissues still bathed with gastric juice? I have observed on the fluoroscopic screen in several cases that this does take place: the bismuth stream could be observed to flow through the pylorus with an immediate reflux into the stomach and through the gastro-enterostomy opening. I believe the greatest benefit of the surgical short-circuiting is due to the prompt discharge of the stomach contents; and if this prompt discharge can be established by medical means in a given case, then surgery has no place for that case.

Dr. E. Libman, New York: Our experience at Mount Sinai Hospital with respect to the relative frequency of duodenal and gastric ulcer coincides with Dr. Mayo's. In the cases of chronic gallbladder and appendix disease with symptoms simulating duodenal ulcer, we find that remissions often occur; in true ulcer the symptoms are a continuous performance as a rule. Moreover, in the appendix cases, there may be pain in the left lower quadrant, which never occurs in ulcer.

Dr. Julius Friedenwald, Baltimore: We have found the relative percentage of duodenal and gastric ulcer to be from 52 to 48 per cent. in cases in which Dr. Finney operated. In duodenal ulcer, by roentgenography we find a hypermotility and a filling defect not present in gastric ulcer. Dr. Finney prefers pyloroplasty for the surgical treatment of this condition.

Dr. C. F. Hoover, Cleveland: There may be a difference between the ease of locating ulcers on the distal side of the pylorus and the proximal side. Dr. Mayo's results were arrived at by the direct evidence of inspection of the serosa, inferentially concluding that the appearance of the serosa is a dependable index of the condition on the inside of the intestine. I recently saw a case of suspected duodenal ulcer in which no ulcer was found at operation, but in which afterward an enormous ulcer was found on the proximal side of the pylorus not indicated by any appearance on the serous surface. Thus gastric ulcers may be missed even after surgical inspection of the organ.

Dr. S. Solis-Cohen, Philadelphia: I wish to protest against laying too much stress on hyperchlorhydria as a positive sign of ulcer either of the stomach or of the duodenum. Also, against accepting hypochlorhydria as conclusive evidence against ulcer. The work of Dreyfuss and Hawk shows that our methods of diagnosis must undergo revision, especially as regards our conceptions of the time of maximal secretion. Their study of the curve of secretion shows very great variations in the time of maximal secretion. The demonstration of hypermotility is a great aid in the diagnosis of duodenal ulcer, and I would strongly urge the personal observation by the physician of the gastric and duodenal movements on the fluoroscopic screen.

Dr. Louis B. Wilson, Rochester, Minn.: I beg to call attention to two types of lesions of the gastroduodenal tract which evidently present unusual diagnostic difficulties. They may be illustrated by two cases: 1. A patient was operated on by a competent surgeon who explored the gastric and duodenal regions without finding ulcer. Later the patient was examined with negative findings by an eminent clinician. He came into the hospital at Rochester moribund. An ulcer of the duodenum was found 3 inches below the pylorus and almost occluding the lumen. 2. A second patient came to the hospital almost moribund and with practically the same history as in the first case. This patient died, and necropsy revealed cancer of the cardia. Thus it would seem that lesions involving the extreme limits of the ulcer-bearing area may readily escape observation even at operation.

Dr. H. G. Wells, Chicago: Dr. Mayo spoke of the recurrence of ulcer at the site of operation, especially after occlusion of the pylorus. Rosenow has studied experimental ulcer formation in Pawlow dogs, and has found that they tend to form at the point of operation. May it not be that the surgeon makes such a favorable site for ulcer formation if infectious foci are not attended to as part of the treatment?

Dr. M. G. Fussell, Philadelphia: As has been said, physicians are constantly treating cases of so-called hyperchlorhydria. When such cases are thoroughly studied under careful dietetic management and with the aid of roentgenoscopy, they separate themselves into their proper classes: those that do not improve under medical treatment are regarded as surgical cases and by the competent physician are referred to the surgeon.

Dr. William J. Mayo, Rochester, Minn.: I wish to emphasize one settled conviction: If the surgeon cannot demonstrate the presence of an ulcer to the satisfaction of the clinician standing 10 feet away, such a stomach or duodenum should not be operated on. My practice is to excise gastric ulcers whenever possible; duodenal ulcers do not lend themselves so readily to excision. I have never known scar tissue in the duodenal or gastric mucosa to stretch any more than such tissue does elsewhere, but it is perfectly true that if obstructive symptoms are due to edema and muscle spasm alone, relief of the obstruction will follow any measure which will abate the edema and spasm. I have found, as have others, that in cases of acute perforation, when the opening is cleancut and recent, the patients recover with simple repair of the perforation, and some get well spontaneously; these ulcers have definite acute appearances and are probably of the type produced by Rosenow. They are unlike chronic ulcers. Those patients who recover under medical treatment should be given a chance to do so.

AMERICAN GYNECOLOGICAL SOCIETY

Fortieth Annual Meeting, held at White Sulphur Springs, W. Va., May 18-20, 1915

(Concluded from page 2016)

A Precise Method of Choosing a Time for Operation in Pelvic Inflammation of Tubal Origin

Dr. Frank F. Simpson, Pittsburgh: The questions of mortality, or postoperative morbidity, and the smoothness of convalescence depend almost entirely on a strict adherence to the following postulates: 1. The patient shall have recovered from her acute illness and shall have regained a satisfactory margin of reserve strength. 2. The temperature shall not have risen above normal a single time for a minimum period of three weeks. 3. There shall have been no marked or persistent rise of temperature following a careful bimanual examination. 4. The inflammatory exudate surrounding the focus of infection shall have been completely absorbed.

DISCUSSION

Dr. Joseph Brettauer, New York: Not only do we minimize the death rate by conservative measures, but we decrease the number of patients for whom we find an operation necessary. Many of these patients do not need an operation in the case of purulent collection in the tubes or in abscess formation. The pathologic and anatomic end-results are a tubo-ovarian cyst, a closure of the tube with adherence of the ovary, and breaking through of the follicle into the tube with a resulting tubo-ovarian cyst, which, in many instances, never requires an operation as there are no symptoms, and it is detected often by mere accident.

Dr. John O. Polak, Brooklyn: I applied the plan that has been outlined by the essayist eight or nine years ago and followed it to the degree of overconservatism, but I think I have saved hundreds of organs. I have been surprised to find later how perfectly the pelvis has regenerated, not only as regards functional ability, but also as to the actual possibilities. For instance, I have seen cases after three or four years absolutely clear up, and pregnancy has occurred after mixed infection.

Dr. Thomas J. Watkins, Chicago: Sometimes it seems of value to operate very soon after these patients have acquired a complete immunity to the infection, taking the temperature and the white count with the idea that there will be some advantage in operating before the adhesions become thoroughly organized. The increased amount of raw surface resulting from operating as soon as immunity has occurred is much greater than the raw surface which remains after operating, if the adhesions have become somewhat organized so as to make the advantage in favor of the later operation. The number of adhesions encountered in operating at an earlier period are undoubtedly greater, many of them being absorbed more readily than they are during a later period.

Dr. J. Wesley Bovée, Washington, D. C.: As soon as Dr. Simpson told me of his method of treatment, I adopted it, and in conjunction with the leukocyte count, I have followed it very thoroughly except in two classes of cases. In the tubercular cases I would operate at once. In the other class I have markedly gone afield, and that is in the acute gonorrheal cases. I am not yet ready to report on my work in this regard. I have not seen the abdominal conditions after this procedure, but I have sterilized the vagina and vulva with iodin and the interior of the uterus by injecting it, the vagina and fallopian tubes, opening the abdomen, separating adhesions, painting all raw surfaces, except normal peritoneum, thoroughly with iodin, putting in drains down to the culdesac before I opened the abdomen, and then draining through the culdesac of Douglas, and I have been pleased with the results. I have done this in the acute cases with a temperature of 103.6 F. For the cases that are more subacute and with lower temperature, I do not think the plan is feasible.

Dr. H. S. Crossen, St. Louis: One has more or less difficulty to determine when to operate on a mass that has passed the acute stage and is in the subacute or chronic stage. It may be two months or two years since the acute infection took place, and it is a question whether or not to do an abdominal operation. We can often determine a gonorrheal infection, and it is safe to operate within three months afterward or two months after sterilization. If it is a streptococcus infection, it is never safe. Streptococci masses are in many instances found self-sterilized. On the other hand, there have been other cases reported in which the infection has lasted as long as six or even twelve years.

Diagnosis of Ectopic Gestation

Dr. George Tucker Harrison, Charlottesville, Va.: One error of diagnosis must be guarded against carefully, and that is to assume that the case is one of hematocele. Such a case I reported some years ago. The deep situation of the fetal sac in Douglas' culdesac and the rough, uneven surface above simulated the characteristic phenomena of an accumulation of blood in the posterior pelvic cavity. Before I saw the woman she had suffered from a chill, followed by fever. When she came under my observation the temperature was 105 F. My diagnosis was infected hematocele. A posterior colpotomy was performed, and on the finger entering the cavity, a 4-months fetus was discovered. Through fear of a fatal hemorrhage, the placenta was not removed, but treated by continuous irrigation. The patient ultimately made a good recovery.

DISCUSSION

Dr. Arthur H. Curtis, Chicago: In the diagnosis of tubal pregnancy, I want to mention enlargement of one ovary due to the presence of a corpus luteum. This enlargement in the case of tubal pregnancy is often no greater than is that in association with normal menstruation, but the ovary is noticeably enlarged and feels about double the normal size.

Dr. Philander A. Harris, Paterson, N. J.: One should not place too much reliance on the physical examination of the pelvis in any stage of pelvic congestion. Ectopic gestation is likely to present varied conditions and symptoms in different patients. The important thing in order to make a diagnosis of the condition, is to get the primary history as well as the initial symptoms of ectopic gestation.

Dr. Herman J. Boldt, New York: A condition which makes the diagnosis difficult is a virulent inflammation of the adnexa. No condition, so far as the history and the objective symptoms go, is so likely to lead to error in diagnosis as that.

Types of Carcinoma of the Uterus

Dr. Lawrence W. Strong, New York: It is customary to call a carcinoma which adheres to the glandular form an adenoma destruens and to speak of the secondarily solid one as adenocarcinoma. This leads to the idea that an adenoma destruens is not a carcinoma in the true sense, while in reality it is a carcinoma from the start. Adenocarcinoma is a rather poor term because it suggests a combination of adenoma and carcinoma. Carcinoma glandulare is the best designation for this type. Benign adenomas of the uterus do not exist, except in the form of adenoma polyposum. Glandular tumors not on the surface are carcinomas from the start. A wedge-shaped excision including normal tissue is to be preferred for a diagnostic specimen in suspicious cases of carcinoma colli. A frozen section is not desirable in collum carcinoma, since a suitable piece mav be removed without anesthesia a few days prior to the operation, allowing careful embedding. No likelihood of implantation metastasis will result in the few days intervening. The objections to frozen sections at operation in suspected collum carcinoma are those of frozen sections in general. In the case of curettings from the corpus, a frozen section should never be attempted. The tissue is too frail for manipulation, and gross inspection is a reliable factor in interpretation.

DISCUSSION

Dr. John G. Clark, Philadelphia: As one realizes the enormous changes which the endometrium undergoes during the twenty-eight cyclic days, the variations are so extreme and so closely simulate in many instances pathologic processes, that the mere question of a hasty diagnosis by frozen section while the patient is on the table is a hazardous one, and will do as much harm as good.

Dr. Frederick J. Taussig, St. Louis: At the Barnard Cancer Hospital we have had 150 cases of cancers of the female genital tract in ten years. Fully three fourths or four fifths of the cases were invariably late cancers. We did not find more than two or three cases in which the tumor lay primarily in the corpus or body of the uterus. We have had cancers of the cervix which have gradually extended up into the fundus, but of cases that started in the fundus and made a large tumor and broke into the peritoneal cavity, we have not had more than two or three cases.

Dr. Herman J. Boldt, New York: The unreliability of frozen sections was brought home to me three or four years ago in a case in which I suspected the presence of carcinoma. I sent a piece of the tissue to the laboratory and waited for the report. This was to the effect that we had a benign condition and I did not do anything, except the plastic work which was necessary. A week or ten days later the laboratory sent a report with an apology for having made an error in diagnosis, based on the frozen section. The condition was malignant, and I had to do a more difficult operation than I would have done at the start.

Bladder Function After Confinement After Gynecologic Operations

Dr. Frederick J. Taussig, St. Louis: While there are gradations of deficiency in bladder function after confinement and operation, we can for practical purposes divide patients into four groups: 1. Those who show at such times no appreciable difference from normal micturition. 2. Those who, while able to void urine spontaneously, do not for a day or two empty their bladder completely. 3. Those who require catheterization one or more times in the first few days, but are then able to void urine without further trouble. 4. Those with prolonged interference of bladder function, who, even when finally able to void urine after several days of catheterization, are able to expel only a part of the bladder contents. The character of the operation, the form and amount of the anesthetic, the age of the patient, the nervousness of the individual, and the degree of sensitiveness of her bladder mucosa are all factors that to a greater or less extent come into play in producing urine retention, and the object of the gynecologist should be to regulate his therapy as far as possible in accordance with the probable factors in his case.

Laboratory Diagnosis of Chronic Infections of the Urinary Tract in Women

Dr. Arthur H. Curtis, Chicago: Chronic infections of the urinary tract can best be diagnosed by one who is actively engaged both in clinical work, including cystoscopy, and in laboratory study. Careful correlation of clinical findings and laboratory methods, with extensive modifications in cultural technic to meet individual cases, is essential. The source of even small amounts of pus in the urine should be investigated; the place of its formation should be definitely localized through the assistance of ureteral catheterization. Persistent pyuria in the absence of a gross bladder lesion is almost invariably due to kidney disease. In those frequent cases of bladder irritability which yield clear, bacteria-free urine, cultures from the traumatized ureteral canal, or from the introduction of a probe into Skene's ducts, may demonstrate the cause of infection. When bacteria are widely scattered or grow with difficulty, a mixture of the urinary sediment with blood followed by making a large number of ascites-blood agar tubes, of high dilution, result in conditions favorable for the development and isolation of the bacteria present. Experience teaches that the chief lesions in urinary tuberculosis are usually renal. In obscure cases, laboratory diagnosis is facilitated by the use of potassium iodid, tuberculin, kidney massage, limitation of liquids, repeated examinations of fresh specimens after high power centrifugation, Petroff's cultures, and the injection of a series of medium-sized guinea-pigs. There is seemingly a tendency to put undue stress on functional urinary tests at the expense of careful routine examination.

Use of the Galvanocautery Knife for Excision of Mammary Tumors for Microscopic Diagnosis

Dr. J. Wesley Bovée, Washington, D. C.: Shortly after installing the Downes electrothermic angiotribe in 1903, I began experimenting with it in the treatment of the uterus and of the breast. For galvanocauterization of the advancing cervical cancer, I devised a cooling vaginal speculum that has proved very efficient, and in breast tumors localized and only suspicious of malignancy, I apply the galvanocautery for excision of the growths, or removal of portions of doubtful tumors for microscopic examination.

In this work, carried out in many cases, I have found but one objection when properly used. This consists of the slowness of the cautery knife when the breasts have been large. This led me to change the technic somewhat. To economize in time I adopted the plan of cutting the tissues for a short distance with a sharp knife, and with the flat sides of the cautery knife, immediately sealing to a considerable depth the sides and bottom of the wound. The use of the knife is again resumed, to be followed by the cautery as before. This process has been continued until the tissue desired is entirely removed, leaving behind a crater with charred boundaries. The hot oil that is fried from the tissues during this procedure is taken up promptly with small pledgets of cotton or gauze in the grasp of forceps and at once discarded. The wound is now covered carefully and the report of the microscopic investigation awaited. If the tissue is reported to be malignant, a radical operation is at once performed. If it is reported to be benign, the surgeon may yet decide, from a consideration of the clinical evidence, to perform a radical operation. If the operation is not to be extended, the wound margins are trimmed of all cooked tissue and the proximal portions of severed milk ducts, and the wound closed completely with sutures. The J. Collins Warren operation I have performed entirely with the knife and cautery with satisfactory results.

The Treatment of Pyelonephritis in Pregnancy

Dr. Raleigh R. Huggins, Pittsburgh: Experiments lead to the conclusion that ascending infection reaches the kidney through the lymphatics more frequently than was formerly supposed. If this is correct, much may be learned from a careful search for the primary focus. This may be found in the bladder itself. Owing to the intimate relationship between the lymph system of all abdominal viscera, and that ot the kidney, the primary infection may lie in the fallopian tubes, appendix or the gallbladder. In severe cases, the diagnosis is usually made without difficulty. The evidence of toxemia, high leukocytosis, and pus in an acid urine, with the presence of colon bacilli in pure culture, are symptoms which are most suggestive. When pain is a prominent feature, pleurisy, infection of the gallbladder, salpingitis, or stone in the ureter or kidney must be excluded. There is usually a pronounced rise in the temperature, and chills. If not contraindicated, cystoscopy with catheterization of the ureters has the same field of usefulness here as a diagnostic measure that it has in the nonpregnant. The important factor in the recognition of this complication of pregnancy is to remember that in the presence of the foregoing symptoms it is the condition most likely to be found. The treatment in some instances requires careful judgment. The mild cases are usually self-limited and respond to rest, proper diet and urinary antiseptics. Irrigation of the pelvis of the kidney should be done if the infection does not yield to simple measures. Severe pyelitis is always a danger for both mother and child, and if the clinical manifestations do not subside promptly under this treatment, then one must consider nephrotomy or the interruption of pregnancy. When surgical measures are not employed in some manner, death not infrequently occurs.

Postoperative Renal Infection

Dr. George Gray Ward, New York: Many instances of obscure and apparently unaccountable elevation of temperature, with concomitant symptoms of septic absorption occurring later in the course of a postoperative convalescence, are cases of renal infection, and they are much more frequent than was formerly believed. In the majority of cases, these renal infections are of hematogenous origin and are due to the colon bacillus. In studying the reports of cases of this disease, one is struck with the frequency with which they follow some operative procedures. The evidence and research tend to prove that the large majority of such renal infections are hematogenous in origin, although some cases may be caused by an ascending infection, either by way of the periureteral lymphatics or by extension up the lumen of the ureter. There are three types of infection, depending on the degree of virulence. They are: 1. Cases which are mild in character. The patient is not severely ill and yields to the thorough flushing of the kidneys by the ingestion of water, formaldehyd, proper diet and rest. The virulence naturally varies according to the particular organism, the condition of the kidney, and the general bodily resistance of the patient. 2. Cases in which the kidneys contain numerous septic infarcts, and minute or microscopic foci which are superficially situated in the cortex of the organ. Decapsulation or incision with drainage usually results in recovery. 3. The fulminating type which is characterized by a profound toxemia, and which is rapidly fatal unless a nephrectomy is done. Fortunately this type of the disease is usually unilateral. If operation is necessary, nephrectomy should not be done unless there are indications for it, as shown by the appearance of the kidney. A decapsulation or nephrectomy with drainage is sufficient in many cases, especially in the colon bacillus infections.

AMERICAN PEDIATRIC SOCIETY

Twenty-Seventh Annual Meeting, held at Lakewood, N. J., May 24-26, 1915

The President, Dr. George N. Acker, Washington, D. C., in the Chair

Cubic Air Space for Institutional Bottle-Fed Infants

Dr. Thomas S. Southworth, New York: The majority of hospital and institutional wards for infants provide 1,000 cubic feet and upward of air space for each infant, and only a few report 600 or less. Ventilation is deemed as important as air space. No allowance of air space is made for the attendants. Separation of the beds plays as large a rôle in limiting the spread of infections as does air space. Bottle-fed babies require more air than nursing babies, and as much as sick babies. Infants, especially bottle-fed infants, should have as much air space as adults, or more. Bottle-fed infants, when retained in institutions for a considerable length of time, cannot be considered as well. Limited air space, involving limited floor space, is an important contributing factor in the morality of artificially fed infants. Free ventilation is also of great importance to the well-being of infants. The mere presence of windows does not constitute ventilation. The example of the more progressive institutions is nullified by state and local regulations licensing those with a minimum air space, in which there is a high mortality.

DISCUSSION

Dr. L. Emmett Holt, New York: Is it preferable to have large hospitals especially for the care of children, particularly young children, or to have children cared for in special wards of large general hospitals? It is hard to get the authorities in general hospitals to realize that children need about twice as many nurses as adults.

Dr. Rowland G. Freeman, New York: Children cannot get well, no matter how much air space there is, if they do not have plenty of freely moving air. The advantages of a general hospital are that there are better facilities for doing good work, and that contact with the men working in other departments often leads to the adoption of methods for treating children that have been found successful with adults.

Dr. L. E. LaFetra, New York: At Bellevue Hospital, it has been found that the babies in the ward do better, the fewer there are, and I think that this is because each nurse, having fewer cases to attend to, can give more individual attention to each. There is often inadequate nursing at night in children's wards connected with general hospitals.

Dr. S. McHamill, Philadelphia: If the managers of general hospitals could be induced to provide the proper conditions, I see no reason why children could not be as well cared for in the wards; but I know of no general hospital that has a sufficient number of wards to provide for all classes of cases in children.

Dr. Henry L. Coit, Newark, N. J.: The reason that an artificially fed infant needs more cubic air space than one that is breast-fed is that the former, often with a subnormal temperature, with no capacity to generate heat, radiates heat from its body more freely.

Dr. Fritz B. Talbot, Boston: Artificially fed infants require a higher temperature because they are not making enough fuel to keep warm.

Dr. Samuel S. Adams, Washington, D. C.: At our institution, we have the mothers come each afternoon and take their children out for an airing. If you cannot get what you want for the babies from the men in charge of a hospital, explain their needs to the ladies' board, and you will usually get what is required.

Parapharyngeal Abscess as Distinguished from Peritonsillar and Retropharyngeal Abscesses

Dr. Henry Heiman, New York: There occurs, especially in children, a form of abscess occasionally mistaken for retropharyngeal abscess, which is really a parapharyngeal abscess, as its site is in the lateral column. It originates in the superior chain of the deep cervical glands, as distinguished from the retropharyngeal glands. These abscesses, as a rule, are cured only by external operation.

DISCUSSION

Dr. Wilder Tileston, New Haven, Conn.: Last winter I saw a case of parapharyngeal abscess in which the abscess perforated internally and was cured without external incision.

Dr. Thomas S. Southworth, New York: There is a peculiar feeling that characterizes peritonsillar abscess. The impression of a vague swelling, without any particular outline, always suggests abscess in the throat.

Dr. L. E. La Fetra, New York: I have seen many abscesses that are not peritonsillar abscesses in the ordinary sense, accompanied by a swelling on the outside. These could be opened from within. They frequently subside, if given time and treated with hot irrigations of the pharynx.

Ductless Gland Therapy

Dr. Royal S. Haynes, New York: In cases of cretinism it is wise to investigate the condition of the pituitary gland. The striking thing in the therapy is the fact that symptoms that might have been due to hypothyroidism clear up under the administration of pituitary gland. In a case of mine there was a striking change in the contour of the hands, ankles, hips, buttocks, thighs and shoulders that could be made to appear or recede by giving or taking away pituitary gland. The effect produced on the child's disposition was also striking. Pars intermedia therapy likewise seems to have done something. We have come only part of the way in this individual case, and these conclusions are merely preliminary.

DISCUSSION

Dr. Charles Herrman, New York: Very frequently more than one gland is attacked. I have been using a tablet containing extracts of three glands, the thyroid, suprarenal and pituitary. I have secured better results in these cases than when thyroid alone was used.

Energy Metabolism of a Two Months' Old Child Fed on a Prolonged Protein-Rich Diet

Dr. S. Raymond Hoobler, Detroit: Protein retained for growth causes no increase in metabolism. Oxidized protein does cause an increase in metabolism, varying with the amount oxidized. The cause of this increased metabolism of protein is the stimulation produced by the amino-acids and their products derived from protein decomposition. When large amounts of protein are fed, with insufficient carbohydrate and fat, even though ample calories to cover the caloric need may have been given, there is a drain on the fat and carbohydrate stored in the body. Protein food, though greatly in excess, cannot be substituted for needed fat and carbohydrate. The proportion fed, as advised and taught, is much in excess of the need.

DISCUSSION

Dr. John Howland, Baltimore: In some work which I did, I was able to show that protein not only produced an excess of heat by being itself consumed, but that, it being impossible to store more than a certain amount of it in the body, it also acted as a stimulus to general metabolism.

Dr. Fritz B. Talbot, Boston: When the protein is increased in raw cow's milk, the visible symptoms of protein indigestion come on much sooner than when other forms of protein are added.

Total Nonprotein Nitrogen and Urea of Blood, and the Phenolsulphonephthalein Excretion in Infancy and Childhood

Drs. Wilder Tileston and Charles W. Comfort, New Haven, Conn.: The phenolsulphonephthalein excretion is somewhat higher in children than it is in adults, and the nonprotein nitrogen and the urea both show less tendency to increase in disease. The practical importance of this lies in the direction of prognosis and treatment. It is an important guide to the diet in nephritis, such as is found in scarlet fever. If the nitrogen is high, it is necessary to restrict the diet; but if one finds normal nitrogen, it is possible to allow more latitude in the diet. From analogy to adults, it seems probable that rising nitrogen will indicate some danger of uremia.

DISCUSSION

Dr. John Lovett Morse, Boston: We have found the phenolsulphonephthalein excretion higher in health in children than in adults. We have also found it little interfered with in a number of cases of nephritis.

Dr. Rowland G. Freeman, New York: One child with severe nephritis passed only 3 per cent. of phenolsulphonephthalein in two hours, but he has practically recovered. That could scarcely occur in an adult.

Dr. Henry Koplik, New York: A low phenolsulphonephthalein excretion is not inconsistent with complete recovery. There may be severe nephritis in children with quite a good phenolsulphonephthalein excretion—65 per cent. in two hours. On the other hand, we had an exception as low as 30 per cent. in a severe case of pyelitis with complete recovery. The test should be made before subjecting a child with nephritis to a surgical operation.

Dr. Wilder Tileston, New Haven, Conn.: I saw a case of nephritis in an adult last year. The phenolsulphonephthalein excretion was zero, yet the woman recovered. The test shows the function of the kidney only at the time it is made.

7 *Calorimetric Observations on Metabolism of Typhoid Patients With and Without Food. W. Coleman and E. F. DuBois, New York.
8 Diabetic Respiratory Quotient. G. Lusk, New York.

1. **Respiration Calorimeter for Study of Disease.**—The story of the Atwater-Rosa-Benedict calorimeter is told by Lusk in brief, comprehensive, perhaps one might say semipopular language. The calorimeter has been successfully used in many experiments on dogs and babies. For the first time direct and indirect calorimetry were found to agree during hourly periods of experimentation.

2. **Respiration Calorimeter of Russell Sage Institute of Pathology.**—The original Atwater-Rosa respiration calorimeter with the improvements added by Benedict, Williams and others has been adapted for clinical study in Bellevue Hospital. The form of the apparatus makes it perfectly comfortable for patients. The accuracy is such that in observations lasting three or four hours the heat production, carbon dioxid elimination and oxygen consumption as determined by alcohol and electric tests can be measured with an average error of 0.9 per cent., 0.6 per cent. and 1.6 per cent., respectively. In periods one hour long the average error for heat measurement was 1.2 per cent., for carbon dioxid 1.6 per cent. and for oxygen 3.2 per cent. The calorimeter never needs more than three men for its operation, and two men have repeatedly made all the readings and all the calculations in hourly periods.

3. **Organization of Small Metabolism Ward.**—The method of collecting twenty-four-hour specimens of urine, described

by Gephart and Du Bois, is a new one. A large number of 20-ounce, round, wide-mouthed bottles with cork stoppers are kept in the ward. These have been etched on the side so that one can write on them with a pencil. At 5 a. m., the time at which the twenty-four-hour period ends, each patient is given a bottle and made to empty his bladder. The bottle is then marked with his name, the date, the hour and minute. The volume is estimated for clinical purposes by comparison with a calibrated bottle of the same capacity. The data are then recorded on a special slip of paper to go to the laboratory and also on the diet chart. A little toluene is added to the urine bottle, which is corked and stored in the ice-box along with the previous voidings of that twenty-four-hour period, each voiding being in a separate bottle. At about 9 o'clock in the morning the laboratory man checks up the bottles with the records on the laboratory slip, and with the nurse's notes takes all the bottles to the laboratory, measures the volume accurately, makes up to volume and analyzes a sample.

The collection of feces is somewhat more difficult. Patients who can get out of bed defecate into a weighed bucket in the commode. This bucket is then weighed again. A little formalin is added and the whole sent to the laboratory where the specimen is thoroughly mixed and one-tenth removed to be dried and added to the other aliquot portions of that period and analyzed. Bedridden patients use a weighed bed pan from which the feces are transferred to a covered bucket for transportation. Most of the patients with acute diseases are given every morning an enema of hypertonic salt solution. To divide the periods, powdered carmin (0.3 gm., 5 grains) is given with the first meal of the period and with the first meal after the period is ended. Experience has shown that it is much easier to determine the exact point of appearance of the carmin in the feces than to find the point of disappearance. When patients are being given enemas it is easier to discover traces of carmin than traces of charcoal. Periods are made as long as possible to minimize the errors of division.

4. **Determination of Basal Metabolism of Normal Men and Effect of Food.**—Seven normal men were studied by Gephart and Du Bois with and without food, as controls for the observations on patients in the metabolism ward. Their average basal metabolism (at perfect rest, fourteen to eighteen hours after their last meal) was 34.8 calories per hour per square meter of body surface. The average basal metabolism of eighty-nine normal men studied by Benedict, Emmes, Roth and Smith was 34.7 calories. The average of the seven men studied in the Sage bed calorimeter in Bellevue and of the five men studied in Benedict's bed calorimeter in Boston was 34.2 calories. As a result the authors have adopted the figure of 34.7 calories per square meter of the body surface as the average heat production of normal men between the ages of 20 and 50 years.

All of the subjects studied in the bed calorimeter were within 11 per cent. of this average. Of the seventy-nine men of normal figure between the ages of 20 and 50 studied by Benedict and collaborators, 86 per cent. were within 10 per cent. of the average and the remainder between 11 and 15 per cent. If therefore, the heat production of a given subject suffering from some pathologic condition is more than 10 per cent. above or below the average it may be regarded as abnormal, but cannot be proved abnormal unless the departure from the average is at least 15 per cent.

Groups of men of weights between 45 and 85 kilograms show a mean heat production within 2 per cent. of the average according to surface area. According to calories per kilogram of body weight the group weighing between 75 and 85 kg. produces 7 per cent. less than the average figure and the group between 45 and 55 kg. produces 9 per cent. more than the average. The conclusion is therefore drawn that among groups of men of varying weights metabolism is proportional to surface area according to Rubner's law and is not proportional to body weight. By using the surface area as a basis one can refer all individuals to a single average normal figure, 34.7. If one uses the body weight as a basis a different normal figure is required for each weight.

5. **Measurement of Surface Area of Man.**—This discussion of the relationship of metabolism to surface area has been based almost entirely on Meeh's formula as determined in 1879. Subsequent observers have found a consistent plus error in this formula amounting to as much as 36 per cent. in the case of very fat individuals. The surface area of the various parts of the body can be determined as follows: A mold of the surface is made by pasting paper over tight-fitting underwear. The area of the mold is then determined by cutting it in pieces, printing a pattern on photographic paper, cutting out the pieces of the pattern and weighing them. To determine the area of each part of the body by linear measurements alone a formula has been devised by the authors on the principle of length times the average breadth times a constant. The sum of these parts gives the total surface area of the body. Five individuals of widely varying shapes have been measured by the Du Boises and the surface area as calculated from the formulas compared with the surface area as actually measured. In the five cases the average error was 1.7 per cent.

6. ***Absorption of Fat and Protein in Typhoid.***—The feces of seven typhoid patients on the high calory diet were analyzed by Coleman and Gephart for fat and protein in seventeen periods of from three to twelve days each in length. The average total fat loss for all the periods was 6.25 gm., corresponding to a percentage loss of 4.3 per cent. No differences were observed in the percentage absorption of fat in the early and later stages of the fever or up to the end of the first week of convalescence, when the intake was relatively large. The average total nitrogen loss for all the periods amounted to 1.57 gm., corresponding to a percentage loss of 11.2 per cent. The constant presence of fat and nitrogen in the feces, even in fasting, vitiates to some extent the validity of the results when expressed in percentages.

7. **Calorimetric Observations on Metabolism of Typhoid Patients.**—The heat production of typhoid patients was measured by Coleman and Du Bois by the methods of direct and indirect calorimetry in a series of sixty-one experiments. The two methods agreed closely, the total divergence being 2.2 per cent. and the average divergence in the individual experiments being 5 per cent. This and the entire absence of abnormal respiratory quotients indicate that in typhoid protein, fat and carbohydrate are oxidized to the same or approximately the same end products as in health, and in their oxidation give off the standard amounts of heat. Therefore the law of the conservation of energy applies to fever patients. The rectal temperature does not always give an accurate indication of the average change in body temperature, and better results are often obtained by well covered surface thermometers. The basal heat production rises and falls in a curve roughly parallel with the temperature. At the height of the fever it averages about 40 per cent. above the normal but in some cases rises to more than 50 per cent. above the normal. The specific dynamic action of protein and carbohydrate is much smaller in the febrile period of typhoid than in health and in some cases seems to be absent. In convalescence it may be greater than normal. In a majority of cases a rise in temperature is accompanied by an increasing heat production and an increasing heat elimination. Typhoid patients can store body fat on an abundant diet while losing body weight and body protein. Loss in weight and loss of protein are usually though not necessarily parallel. There is a toxic destruction of protein in typhoid. This is shown by the fact that patients have a distinctly negative nitrogen balance on a diet which contains more than enough calories to cover the heat production.

9. **Narcotic Drugs in Phlorhizin Diabetes.**—It is concluded by Sansum and Woodyatt that their experiments offer no evidence that acetaldehyd is itself convertible into glucose or capable of promoting any new formation of sugar, which is in harmony with the observations of Friedmann that in liver perfusion experiments acetaldehyd is an acetone former, and not a sugar former. It is also concluded that the hypothesis that acetaldehyd promotes a new formation of sugar from fat has no more support than that which assigns to epinephrin a similar power. The hypotheses of antiketogenesis and diabetes which are based on the assumption that acetaldehyd promotes a new formation of sugar from fat are wholly untenable.

18. **Physiology of Reproduction in Domestic Fowl.**—From the evidence presented by Pearl and Surface it appears that the substance of the anterior lobe of the pituitary extract body of the cow, when injected into the abdominal cavity of hens in which the ovary is in a completely resting condition, does not cause an activation of the ovary, in the sense of inducing ovulation at an earlier date than that at which it would normally occur.

26. **Starvation and Obesity.**—Folin and Denis report on the fasting metabolism of two extraordinarily fat women, both essentially normal except with reference to their obesity. The analyses included practically all the determinable urinary constituents (except the metals), but chief interest concerned the acetone bodies. The results obtained suggest, however, that one perfectly safe, rapid and effective method of reducing the weight of very obese persons is by a series of repeated fasts of increasing duration, using the ammonia or *B*-oxybutyric acid elimination as a guide to the length of each fast. Two conclusions with reference to the nitrogen elimination suggested themselves: First, that the obese destroy less body protein during moderate periods of starvation than others; and, secondly, that with repeated fastings their adaptation to the complete utilization of body fat, which was indicated by a retarded and diminished excretion of actone bodies, is also accompanied by a sparing of the body protein. It is concluded that obesity is not a predisposing or contributing factor in the onset or intensity of the acidosis of starvation. The total acetone excretion with the breath in starvation is quantitatively insignificant (at most 1 gm. per day), and the notion, current among clinicians that they can smell acetone "all over the room" when a case of acidosis is present, is erroneous. By repeated fasts of moderate duration the obese acquire an increased ability to starve without the production of acetone bodies. The obese lose less body protein than others in the course of moderate periods of starvation (four to six days) and on repeating the fasts the losses of body protein become still smaller. Successive moderate periods of starvation constitute a perfectly safe, harmless and effective method for reducing the weight of those suffering from obesity.

31. **Influence of Natural Fats on Growth.**—The new features of this communication are summarized as follows: The failure of lard to promote growth in the same manner as other natural fats (namely, butter-fat, egg-yolk fat, cod liver oil) do, is not attributable to deteriorating changes arising from heat or chemical agents in the commercial manufacture of the product. Heating butter-fat with steam does not destroy its growth-promoting efficiency. Beef-fat also renders the inefficient diets used by us more suitable for producing growth in rats than does lard. When butter fat and beef fat are subjected to fractional crystallization from alcohol, the growth-promoting factor remains in the mother liquor "oil" fractions. The fractions containing the fats with high melting points are ineffective. Some quantitative aspects of the growth-promoting efficiency of the natural fats are discussed.

32. **Influence of Oxidizing Substance on Immune Reactions.**—In order to study the influence of increased oxidation on other immune reactions, Arkin has used sodium iodoxybenzoate, an organic peroxid, which has a marked effect on oxidative processes in the body. He found that sodium iodoxybenzoate stimulates the production of hemolysin and agglutinin in rabbits when injected intravenously shortly after immunization. The results show that there is a close relationship between the production of antibodies and the oxidative processes. The substance probably acts by accelerating oxidations in the tissues which are the site of antibody formation. This acceleration is produced probably by some catalytic effect of the sodium iodoxybenzoate, for the small amount of oxygen injected into the circulation could not have this effect. That the action of this compound is exerted on the tissues is shown by the fact that the substance diminishes the intensity of the local allergic reaction

in sensitized animals. It has a marked inhibitory action on the local tuberculin reaction in tuberculous animals. This action is due to a more active oxidation by the tissues of the toxic substances which cause the inflammatory reaction. Whether these toxic substances acted on are the ones present in the tuberculin or are produced at the site of the inflammatory reaction in the tuberculous animal has not been determined. However, sodium iodoxybenzoate has the power of oxidizing tuberculin in vitro, and this oxidation is accompanied by a decrease in the toxicity when injected into normal animals.

All these results suggest that there is a close relationship between oxidation and immune processes, for a substance which is an organic peroxid stimulates the production of antibodies. It probably sets up in the tissues, which are the site of antibody formation, a more active oxidation, not the result of the amount of oxygen which it contains but because of some catalytic effect. That the compound can influence tissue oxidation is shown by its inhibitory action on the local allergic reaction, a reaction due, in part at least, to interference with oxidation at the site of the reaction.

33. **Human and Bovine Tubercle Infection.**—The strain of tubercle bacilli isolated by de Besche from the mesenteric gland of a tuberculous child which on first examination had to be classified as "atypical," on closer study proved to be a "mixed virus," since both types of tubercle bacilli were isolated from the cultures. The individual from whom the cultures were isolated had been infected with tubercle bacilli both of the human and of the bovine type.

34. **Etiology and Production of Erythema Nodosum.**—A series of cases are recorded by Rosenow in which a bacteriologic study of the blood, of the probable infection atrium, and of excised nodes was made with almost uniformly positive results, lesions quite like those of erythema nodosum developing in animals on intravenous injection of the organisms isolated. A diphtheroid, gram-staining, polymorphic, nonmotile, nonspore-forming bacillus producing small, round colonies in dextrose agar, and small, gray, or yellowish, nonhemolysing colonies on blood agar, and having a wide range of fermentative power, was isolated from erythematous nodes removed in each of eight cases. The same organism was isolated at the same time in pure culture from the blood in two cases, and in conjunction with B. welchii in one case. The infection atrium would appear to have been the tonsils so far as the clinical history in two cases indicates; in three others the tonsils contained an organism which produced hemorrhages in the skin in animals; in another case the organism was found in a superficial ulcer in the throat, and in still another in an abscess of a tooth. In three cases the infection atrium was not apparent nor could it be determined. In four of the cases there was a definite but mild arthritis; in three, myositis or fibrositis; in two endocarditis; in four lymphadenitis; in two pericarditis; and in three, mild nephritis. All of the typical cases ended in recovery.

35. **Starch Agar.**—The medium on which Vedder has had the best success in cultivating the gonococcus consists of beef infusion agar to which 1 per cent. of starch has been added.

36. **Complement Fixation in Whooping Cough.**—Fifty-one cases were studied by Winholt, twenty-two cases with a history of pertussis, and twenty-nine cases without any symptoms or recent history of pertussis. Except for a few minor changes the test for complement fixation has been made as described by Bordet and Gengou. His results indicate that complement fixation in pertussis is obtainable about two weeks after the onset of the disease. The fixation is not as strong at this time as it is eight to ten weeks after the onset. At eight months after the beginning of the whoop, the reaction may still be present but not marked. When the influenza bacillus is used as antigen with serum of pertussis patients, no complement fixation occurs. The serum of patients with pertussis, or convalescing from pertussis, agglutinates the bacillus pertussis, but the concentration of the agglutinin varies greatly. The influenza bacillus is not agglutinated by the serum of pertussis patients in dilutions above 1-20. These results, as well as the results of the tests for complement fixation and agglutination with the serum of immunized rabbits, indicate no relationship between the bacillus of pertussis and the bacillus of influenza; the results with the serum of patients indicate that the bacillus pertussis has a specific relationship to whooping cough, but that the influenza bacillus has not.

40. **Natural Hemolysins in Human Serum.**—Sheep and dog according to Kolmer and Casselman are not the ideal hemolytic systems for performing complement fixation work with human serum, but hog, rat, chicken, horse, rabbit, or guinea-pig systems are preferable, depending from the practical side on the ease with which the authors can obtain these corpuscles and their specific amboceptors.

41. **Typhoid Epidemic Caused by Paragaertner Organism.**—An epidemic resembling in many ways a water-borne typhoid epidemic was investigated by Robinson. A careful bacteriologic examination of feces of patients was negative for typhoid, but an organism was found which seemed to have the cultural characteristics of the paragaertner group.

42. **Complement Fixation in Acute Rhinitis.**—With the use of the bacillus rhinitis as antigen, fixation of complement was obtained by Howell with the serums of persons with rhinitis and of persons injected with the bacillus after it is killed by heat. The fixation is most marked a few days after the onset of the infection and lasts only a short time. Serums of normal persons and of patients with various infectious diseases do not give complement fixation with the bacillus rhinitis. The serums of patients with acute rhinitis do not give fixation of complement, except occasionally when suspensions of various bacteria (pneumococci, staphylococci, streptococci, influenza bacillus, fusiform, pseudodiphtheric bacilli, etc.) ordinarily regarded as closely associated with rhinitis, if not the actual cause thereof, are used as antigens. These results indicate that the bacillus rhinitis bears a specific relationship to acute rhinitis as ordinarily observed in this region.

44. **Ferments in Blood in Infectious Diseases.**—Falls claims that in the infectious diseases the ferment content of the blood is increased above the normal in most cases. Acute infections in which the reaction between the infecting organisms and the body defenses takes place outside the blood stream, cause relatively little increase in the ferment content of the blood serum, as measured by this method.

47. **Bacteriology of Rhinitis.**—The bacillus rhinitis, in Tunnicliff's opinion, has some etiologic relation to acute and chronic rhinitis on account of its almost constant presence in the nose in such cases, its general absence from the normal nose, its ability to produce rhinitis experimentally with recovery in pure culture, and on account of the production, in cases of acute and chronic rhinitis and in persons injected with the bacillus, of specific antibodies (opsonins and complement-binding bodies).

48. **Immunity of Mice to Implanted Tumor.**—Tyzzer found that repeated inoculations of various tumors do not produce sufficient immunity to overcome an established tumor resulting from the first implant. It has been thus far impossible to immunize the Japanese waltzing mouse against tumor J. w. A, not only by repeated injections of large doses

of dried tumor in suspension but also by defibrinated blood or living tumor. The individuals of this variety of mice show such uniform susceptibility that the transference of the tumor from one individual to another appears not to involve any appreciable modification of the environment. The lack of immunity reaction is seen in the frequency of metastases and in the absence of instances of retrogression. This tumor as propagated in the waltzing mouse reproduces very closely, therefore, the conditions under which spontaneous tumors develop.

Implants of the Japanese waltzing mouse tumor J. w. A grow for a time as vigorously in nonsusceptible as in susceptible mice. In the former at the end of a fairly constant period of six or seven days inflammation together with degenerative changes become evident in the host tissue surrounding the tumor implant, while the latter is then secondarily affected through thus having its support of healthy growing tissue destroyed. In nonsusceptible mice which have been previously inoculated with tumor tissue, tumor implants are destroyed by a process in every respect similar to that just outlined, except that it follows soon after the introduction of the tumor tissue. Since this is accomplished more promptly, the reaction is found to be subsiding in immunized series at the time that it is just appearing in control series of nonsusceptible mice. Only living tumor is capable of exciting this reaction and as the tumor becomes necrotic the cellular infiltration quickly disappears. A similar inflammatory reaction occurs also around second implants of the Ehrlich Strain II in common mice, although these are known to be partially immunized by the first implant. This reaction is evidently based on the production in the immune animal of material which in combination with material elaborated by the tumor produces local injury to the tissues surrounding the implant and thus indirectly destroys the latter.

49. **Atypical Hemorrhagic Malignant Hepatoma.**—True hemangiosarcomas primary in the liver according to L'Esperance undoubtedly have been observed, but occur usually in early life; they are extremely rare and should not be confused with the atypical malignant tumors occurring in adult life. Endothelioma and perithelioma derived from the capillary structures of the liver are reported but without sufficient evidence, in the author's opinion, to support the view that they are true endotheliomas. True chorioma primary in the liver has not been proved to exist. The resemblance to chorioma observed in certain cases proves on analysis to be very superficial, since these tumors do not show the typical Langhans cells and syncytium as do true choriomas even when heterotopic. Primary atypical carcinomas of the liver parenchyma show wide variations in histologic structure, but usually exhibit in certain portions the definite arrangement of rows of cells simulating liver cords, with obvious transformation of hyperplastic liver cells into tumor cells.

The consideration of cirrhosis as an etiological factor in these cases does not appear to have sufficient justification. In the three cases which L'Esperance has had opportunity to study there was no cirrhosis, which rather favors the view that cirrhosis is not necessary in the development of this class of neoplasms and when present probably is of secondary importance. Reviewing these conclusions: The evidence appears very strongly to favor an epithelial origin for these atypical tumors, and it seems advisable, therefore, to classify them with the primary diffuse carcinoma derived from liver parenchyma. The term "atypical hemorrhagic malignant hepatoma" seems most suitable.

51. **Promitosis in Tumor Cells.**—The assumption of very primitive biologic mechanisms, not ordinarily possessed by normal metazoan cells, is believed by Schultz to be a characteristic feature of the cells of rapidly growing tumors. Among such mechanisms are very simple forms of division, as well as such which have always been termed atypical mitoses. Of these simpler division forms, one, which has been encountered in several varieties of malignant tumor, is characterized by the primary division of a nucleolus or, better, karyosome, the rest of the division simulating an amitosis. The participation of the karyosome in this process is believed to indicate the return on the part of the tumor cell to that condition in which the division sphere is permanently intranuclear, both in rest and in division. Other division figures, studied in a rapidly growing giant-cell sarcoma of the esophagus, would indicate that the kinetic center which has taken an intranuclear position can become temporarily extranuclear during the later stages of a form of division which simulates mitosis. Tumor cells, in their return to primitive biologic mechanisms, may be expected to show those simpler promitoses from which the mitosis of metazoan cells has been developed.

52. **Local Action of Lead.**—Within endothelial leukocytes and endothelial cells inorganic lead is changed to a compound that is soluble in albuminous fluids, in which form it passes into the blood producing a "stippling" of the corpuscles, and into liver cells producing in them a basophilic granulation. The basophilic hyaline change in both red corpuscles and liver cells, McJunkin claims, is due to the immediate presence of lead as is shown by subjecting the preparations to prolonged treatment with an alkaline sulphid. The reason for the failure to produce by the administration of lead for a few months (in the case of one monkey, eight months) lesions other than local lesions at the site of application and the basophilic granulation of the liver cells and red blood corpuscles is not apparent.

54. **Influence of Removal of Suprarenal.**—The result of experiments presented in this communication and in a previous one are summed up by Friedman as follows: 1. Suprarenal hypofunction causes lesions in the stomach in rabbits and in dogs. 2. An excess of thyroid gland, as produced by repeated intravenous injections was probably responsible for the gastric lesions of two dogs and of one rabbit (of four animals experimented on). 3. Thyroid hypofunction caused the appearance of duodenal lesions in five animals out of six. 4. An excess of adrenalin, produced by repeated injections of the drug, led to the appearance of lesions in the duodenum of dogs. 5. The simultaneous production of suprarenal and thyroid hypofunction did not lead to any lesions in the stomach, nor in the duodenum in rabbits. 6. When after removal of one suprarenal the other became hypertrophied, lesions were seen in both viscera of three rabbits and in the duodenum of one. From Friedman's experiments it seems probable that gastric lesions might be dependent on suprarenal insufficiency as well as on an excess of thyroid gland, duodenal lesions on the contrary on thyroid hypofunction as well as on excess of adrenalin. Gastric and duodenal lesions might be dependent on the alternating effect of hypofunction and hyperfunction of the suprarenals.

55 *Spinal Cord in Case of Isolated Atrophy of Small Muscles of Hands. M. E. Morse, Worcester, Mass.
56 *Cerebellar Syndrome. W. F. Schaller, San Francisco.
57 Angioma of Cerebellum. L. Newmark, San Francisco.

55. **Case of Isolated Atrophy of Small Muscles of Hands.**—A case of isolated atrophy of the small muscles of the hands, of uncertain etiology, occurring in a man 58 years old, of alcoholic habit is cited by Morse. The essentials of the lesion in the cord were: 1. Atrophic and degenerative changes in the nerve cells, widely distributed in the gray matter, but more prominent in the postero-lateral and post-posterolateral columns. 2. Cell losses in the posterolateral and post-posterolateral columns. 3. Vascular changes, which consist in a thickening and a mild perivascular lymphocytic infiltration, the latter being confined almost entirely to the sulcal arteries and their branches to the anterior horns. 4. A characteristic distribution, the lesion commencing in the middle of the seventh cervical and extending through the first dorsal segment.

56. **Cerebellar Syndrome.**—Of the more dependable symptoms in cerebellar disease Schaller classes ataxia of cerebellar type, asynergia, adiadochokinesis and cerebellar catalepsy; falling symptom, and variations from the normal in the functional labyrinth tests and the pointing reactions of

Bárány. Less dependable symptoms are those produced by intracranial pressure: Nausea, vomiting, vertigo, choked disks and nystagmus.

63 Diabetic Type of Pyorrhea Alveolaris. D. B. Freundlich, New York.

58. **Preventive Measures in Chronic Diseases of Heart, Kidneys and Arteries.**—The various agencies which should be utilized in public health education are catalogued as follows by Wile: 1. The maintenance of a health bulletin to be distributed by mail, to be sent to schools, public libraries, to social and philanthropic agencies. 2. The development of moving picture scenarios so as to present health factors to the eyes of the public. 3. The encouragement of short sketches dealing with health problems for productions at vaudeville houses, and aid in writing them. 4. The use of posters on public billboards. 5. The organization of health exhibits in vacant stores and compact traveling exhibits for loan purposes to schools, shops, factories, churches and similar institutions. Such exhibits should be of two types, namely, a general "keep well" exhibit constructively showing how to live, and special exhibits depicting and illustrating such particular health problems, as the prevention of tuberculosis and the care of the baby, and plotted curves, photographs, cartoons, drawings, papier maché models and various other appealing exhibits will be required. 6. The maintenance of frequent press notices concerning facts necessary for public-health education. 7. The organization of a staff of capable lecturers within the department and the securing of cooperation from the department of lectures of the Board of Education with a view of increasing the number of lectures on health topics to the adult population attending the lectures at public schools. Further, the organization of a volunteer lecture corps to be recruited from public-spirited physicians, nurses, etc., interested in public health. 8. The distribution of brief, concise and to-the-point health talks to parents and industrial workers through the medium of the children of the public schools, the agents of the Metropolitan Life Insurance Company, and the secretaries of organizations, of churches, directors of Y. M. C. A. branches and such organizations as the Boy Scouts, the Campfire Girls, the state militia, and other organizations now existent. 9. The establishment of a health day to be celebrated by special exercises in schools, churches, etc., dealing with health problems. 10. Active participation in the programs of conferences on charities and corrections, to indicate the relation of various social problems to public health.

70 *Abdominal Pain, Its Significance and Diagnostic Value. J. B. Deaver, Philadelphia.
71 *Case of Perforation of Esophagus followed by Septic Infection and Ending in Recovery. G. M. Coates and R. M. Goepp, Philadelphia.

68. **Surgical Treatment of Gastric Ulcer.**—That the incidence of gastric ulcer has been constantly increasing with the introduction of methods for earlier and more accurate diagnosis is claimed by Frazier. That gastric ulcer is often a precursor of cancer has been proved conclusively; hence a review of statistics as to the incidence of the latter disease should serve as a guide in our estimation of the frequency of ulcer, and should further emphasize the importance of the early diagnosis and treatment of gastric ulcer. With the various methods now at our disposal, the diagnosis of gastric ulcer is not a difficult one; there are, of course, exceptional cases. The history should always arouse suspicion; the roentgenogram confirms in nine out of ten cases. Frazier advocates surgical intervention in chronic ulcer of the stomach and duodenum, because the effect of surgical intervention is more enduring and more satisfactory than that obtained by medical methods. The nearer to middle life the patient is, the more urgently does Frazier impress the need of an operation, for fear of cancer. Gastrojejunostomy alone, has left a trail of failures. Gastrojejunostomy with exclusion and infolding of ulcer is a distinct improvement. Transverse resection offers greatest assurance of a complete enduring "cure."

70. **Abdominal Pain.**—When, after an abdominal operation, pain makes its appearance on the second or third day or later, Deaver says, three conditions are chiefly to be considered, simple distention, peritonitis and obstruction. The pains of distention and obstruction are as a rule colicky and wavelike, while that of peritonitis is more steady, diffuse and unremitting. In the first case the pain is quite definitely related to peristalsis, but in peritonitis no such relation is observed. Peritonitis causes tenderness and muscular rigidity which are absent in distention or mechanical obstruction. The temperature is an unsafe guide but is more likely to be elevated in peritonitis and the pulse is more markedly affected in rate and volume. As between simple distention and obstruction, the difference in the severity of the symptoms is the chief guide. When the intra-abdominal conditions present both obstructive and inflammatory characteristics, as in the ileus which accompanies general and some local peritoneal infections, the difficulties are markedly increased. The most important single feature in differentiation is the character of the pain, whether wavelike and intermittent or steady and associated with tenderness.

71. **Perforation of Esophagus Followed by Septic Infection.**—The interesting features of the case cited by Coates and Goepp are the number of different septic manifestations—urticaria, pleurisy, nephritis, polyarthritis and severe secondary anemia, the rapidity of their onset and equally rapid subsidence. The prostration during the height of the attacks, that is, during the period of severe arthritis, which was the prominent clinical feature of the case, was in proportion to the severity of the nephritis and the anemia, and for a time the prognosis was regarded as extremely doubtful. The recurring attacks of intense and generalized urticaria suggest an effort at elimination of the toxins and were regarded as not altogether an unfavorable symptom. From the therapeutic point of view the gratifying effects of hypodermoclysis on the urinary elimination and the rapid repair of the blood under hypodermic administration of iron are interesting.

78. End Results of Round Ligament Fixation.—Up to Jan. 1, 1914, Kohlman operated on 216 cases by this method. He has communicated with and examined 70 of these cases, 60 of whom were found in good condition in regard to the position of the uterus and are free of important symptoms. In 4 cases the uterus was found in retroversion complicated with moderate local symptoms. Six cases have been operated on again, and the uterus was found in normal position, the ligaments only slightly elongated; operation was required on account of recurrent disease of the adnexa. Eight patients have been pregnant since the operation, two twice, and have passed through a practically normal delivery. The cervix was found in the beginning of labor somewhat drawn to the back but conditions rectified themselves during the progress of labor. In two cases only a low forceps was employed on account of delayed expulsion. Two cases came under his observation quite recently in the eighth month of pregnancy, and so far they have progressed without any pain or discomfort.

80. New Method in Disposing of Stump of Appendix.—In Carter's method the appendix is caught near the base with a forceps and clamped, and if not ruptured, or likely to, it is left until suture is inserted, otherwise it is cut off just above the clamp and removed. Then take a suture (catgut preferred, No. 2), in a straight or curved round needle, inserting it into the bowel about ¼ of an inch from the base of the appendix and extending about ¼ of an inch beyond, the needle running parallel with the base of the appendix when it is brought out through the bowel, the suture including about one third of the appendicular base. Two more stitches are taken in like manner around the appendix causing the sutures to form a triangle around its base. As the sutures extend within the bowel, the assistant with a pair of thumb forceps pushes down on the appendiceal stump, therefore inverting it into the bowel, when traction is made on the suture and tied. After the suture is tied it is Carter's custom to place two or three Lembert's sutures over same to reinforce and at the same time cover over the small bit of catgut that is without the serosa.

4. Six Specimens of Great Bowel Removed by Operation.—Attention is directed by Keith to the knowledge which can be gleaned from a systematic examination of such specimens as are removed by operation from patients suffering from the incurable forms of colitis and of intestinal stasis. He states that the pathologic condition cannot be explained on the simple basis of mechanical obstruction; our only hope of penetrating the secrets of the disease is a fuller knowledge of the anatomy and physiology of the great bowel, and its manner of action in health and disease. His examination has convinced Keith that the operation of colectomy is justifiable in the cases in which the pathologic conditions seem to be beyond repair.

6. Bacterial Activity in Alimentary Tract.—The main facts which are substantiated by Mutch are briefly summarized as follows: Dilatation of the duodenum is usually associated with gastric stasis. Dilatation of the duodenum varies directly as the degree of ileal stasis, and—apart from this—shows no relationship to the ileal kink. Epigastric tenderness in constipated subjects is usually experienced over the third part of the duodenum; not over the pylorus. Typical "hunger" pain may arise when food in the lower ileum produces duodenojejunal obstruction. A pure culture of a long-chained gram-positive hemolysin-producing streptococcus was obtained from the duodenum of a man with severe anemia and pigmentation. The richness of the living bacterial flora of the colon is immeasurably greater than that of the last coil of the ileum. The degree of ileal infection with coliform organisms is proportional to the degree of ileal stasis. A marked ileal kink acts as a protective barrier against invasion of the ileum by coliform organisms.

The infection of the ileum with coliform organisms and the dilatation of the duodenum vary in a parallel manner. The infection of the ileum with coliform organisms is uninfluenced by the acidity of the gastric secretions. Urine of constipated patients often contains urobilin. Urine from constipated patients often contains hydroxyphenylacetic acid. The excretion of the more complex tyrosin decomposition products varies directly as the degree of ileal infection with coliform organisms. The excretion of tryptophan decomposition products varies directly as the degree of ileal infection with coliform organisms. The excretion of indoxyl, indolacetic acid and hydroxyphenylacetic acid is uninfluenced by an infection of the ileum with streptococci or with the *B. acidophilus* of Moro. The excretion of the last-mentioned substances varies in proportion to the degree of ileal stasis.

The excretion of tyrosin derivatives is uninfluenced by hyperchlorhydria, but increased by hypochlorhydria. The excretion of tryptophan derivatives shows the same relationship to gastric secretion as does that of the tyrosin derivatives. The excretion of indoxyl, indolacetic acid, hydroxyphenylacetic acid and urobilin is almost entirely abolished by ileocolostomy. An infection of the ileum with *B. aminophilus* occurs in constipated patients with a subnormal blood pressure, but not in other constipated patients. Chronic infection of the ileum with *Staphylococcus citreus* has been shown to be present with chronic septicemia due to the same organism, and with the chronic joint, lymphatic and splenic changes classified as Still's disease. The constitutional changes and those in the joints, lymphatic glands and spleen were abolished by colectomy. Fifty-five ileums of patients without Still's disease were free from *Staphylococcus citreus.* The hands of constipated patients recover from exposure to cold at a very much slower rate than do the hands of healthy subjects. A patient with Raynaud's disease was found to be the subject of chronic intestinal stasis. In his ileum were large numbers of an unusual gram-positive bacillus and a short streptococcus. Colectomy restored his hands to a normal condition, in which they showed normal reaction after exposure to cold. His ileal flora formed pressor bases from peptone.

7. Roentgenologic Studies of Large Intestine.—According to Barclay, the ileocecal region is in very close association with the duodenopyloric region. There is evidence of two separate reflexes between the ileocecal valve and the pylorus, namely, one from the stomach to the ileocecal valve, and another from the ileocecal valve to the stomach, the latter (the ileopyloric reflex) being responsible for appendix dyspepsia. Ileal stasis is, up to a point, physiologic. Pathologic ileal stasis is usually associated with adhesions in this region, most frequently appendicular in origin. In all these examinations it is essential to prepare and examine patients on a routine plan. A scheme that includes "double" feeding is useful. The appendix can be seen in a certain proportion of cases, and, by palpation, it can be detected whether it is fixed or lying free. The normal movement of feces through the large intestine is by "mass" movement, in which a large column is moved through a long section of the colon in a few seconds; these movements take place probably some three or four times a day. The "mass" movements do not occur in the cecum.

Constipation occurs as the result of stagnation: (*a*) In the sigmoid and rectum, namely, inefficient defecation, or dyschesia; and (*b*) in the cecum, constipation proper. Constipation proper is probably the result of a defect in the mechanism of the "mass" movement. It is suggested that for the efficiency of this movement it is necessary that a sphincteric contraction should be present. The competency or otherwise of this sphincter, or *point d'appui*, determines whether the "mass" movement, when it occurs, propels all the feces forward, or sends some of them back into the cecum. The large, sloppy cecum is the result of this inefficiency, and not the cause of constipation. The opaque meal seldom gives information as to early neoplasms of the large intestine—it is only after the bowel becomes distended that information is obtained in this way. All suspected cases of neoplasm of the large bowel should be investigated by means of the opaque enema.

9. **Colectomy for Hirschsprung's Disease.**—Of seven cases—all examples of the disease in its most extreme form seen by Barrington-Ward, two patients died as the result of the operation, one from shock, and one from the effects of a severe accidental hemorrhage at the operation. Of the five remaining patients, four are perfectly healthy normal children without any distention or constipation. One has still some slight distention; but this is attributed to tuberculosis of the mesenteric glands, which has been a complication throughout. The most recent of these operations was ten months ago, and it is therefore reasonable to hope that their cure is permanent.

12. **Homobone-Graft in Case of Sarcoma of Radius.**—In Robertson's case there was a swelling the size of a tangerine orange at the lower end of the left radius. This swelling was rounded, hard, nonfluctulant, most prominent in front, and did not interfere with the movements of the wrist joint. The diagnosis of periosteal sarcoma was made, and the patient having refused amputation, it was determined to remove the tumor by a resection of the lower ends of the radius and ulna and to restore the arm by means of bone grafts. All tumor tissue was very thoroughly removed, and the wound prepared for the reception of the graft by careful hemostasis. The graft, composed of appropriate portions of bone with the periosteum and carpal ligaments, from a patient whose arm was being amputated at the shoulder, was then prepared and placed in position. The carpal ligaments were stitched with great care, especially posteriorly, and the radius was wired to secure fixation.

For some days after operation the patient had considerable pain and a slight evening rise of temperature, but the dressing was left intact until February 25, when on its removal the wound was found healed. From that time massage and passive movements were carried out daily, the arm being kept in anterior and posterior flat splints in the intervals. A roentgenogram taken at this time showed the radial graft in good position, radial deviation of the ulnar graft, and some slight rarefaction of the lower end of the native radius. When the patient was dismissed there was a slight degree of mobility between the ends of the grafted and the native bones, and movement at the wrist joint was not free. Eleven months later there was marked evidence of local recurrence of the tumor, but no metastases in the lymph glands or in the lungs. Amputation was performed above the elbow. The wrist joint had not been reformed, a firm fibrous tissue intervening between the grafts and the native carpal bones. The tumor separated the ends of the graft and native bones, and invaded the graft radius equally with the native one. The native and graft ulna were also to some extent involved. A small isolated tumor nodule was seen in the substance of the semilunar bone. Apart from tumor invasion, the grafts had all the appearance of living healthy bone.

27 *Loose Scrap of Shell Removed from the Right Ventricle; Recovery. Beaussenat.

27. **Scrap of Shell Extracted from Interior of Heart.**—This case illustrates anew the remarkable tolerance of the heart, the scrap of shell weighing 1.5 gm. and measuring 1 cm. long by 3 mm. thick. It had been in the heart for four months and a half, during which there had been dyspnea on exertion and precordial distress, especially at night, occasionally leading to syncope. Roentgenoscopy showed the scrap of metal following the movements of the heart. By moving gently and speaking slowly the young man kept his symptoms mild. There were no murmurs or other signs of anything wrong in the heart, except a thrill at the apex. The foreign body was supposed to be in the pericardium, but when this was opened it could be felt loose in the right ventricle. The myocardium was then brought out of the pericardium and two loops of silk, about 5 or 6 mm. apart, were passed lengthwise through the ventricle wall. With these the heart was held firm and the lips of the incision held apart. The spurting black blood was checked with the left index finger, while the heart was held between the thumb behind and the three other fingers in front. During the diastole the scrap of metal was seized with forceps after one ineffectual attempt. The heart was then sutured with silk. For three days the dyspnea was intense, the pulse weak and irregular, the facies drawn and pale, but the patient recovered and may now, two months later, be considered actually cured. Recovery at first was delayed by three brief attacks of cough and blood-stained sputum, evidently from embolism in the lungs. Now auscultation gives normal findings and electrocardiography shows merely a predominance of the left ventricle. (See also Paris letter, June 5, p. 1927.)

28 *Clinical Pictures and Treatment After Wounds of Peripheral Nerves. J. and Mme. Dejerine and J. Mouzon.

28. **Wounds of Peripheral Nerves.**—A number of illustrations are given to show the clinical pictures presented when the trunk nerve in the arm or leg has been severed or is suffering from compression or is recuperating after an operation. A number of typical cases are described, with the operative measures applied and the results to date. Any sign of spontaneous recuperation is regarded as a formal contraindication to operative measures unless the improvement is persistently restricted to sensory fibers. The necessity for respecting the nerve tissue proper in any operation is emphasized anew. Even pushing a sound nerve aside is liable to entail a tendency to paresis, pain and reaction of degeneration for a couple of months, and a regenerating nerve is even more sensitive.

32 *Pathogenesis and Treatment of Constitutional Purpura. (Die essentielle Thrombopenie.) E. Frank. Commenced in No. 18.
33 Universal Orthopedic Apparatus. (Kombinationsapparat.) M. Wunsch.

30. **Examination of Spinal Fluid in Syphilis.**—Neisser deplores the fact that many physicians still have failed to master the technic of examination for spirochetes, so that far too often syphilis fails to be recognized in the early phases, when it can be so much more easily stamped out. It would be an advantage also if all physicians made a point of examining the serum in all cases of illness of any kind, with and without a history of venereal disease.

Examination of the fluid drawn by lumbar puncture is equally indispensable at certain times. When everything indicates that the treatment has done its work and the course can be suspended, then examination of the spinal fluid will reveal whether this is really the case. Negative findings in the fluid do not absolutely guarantee that the central nervous system is entirely free from syphilis; but at least we have done our duty in such cases.

It sometimes happens that the Wassermann persists positive, notwithstanding repeated vigorous courses of treatment. The question is, should we keep on repeating the courses indefinitely? Here, again, the spinal fluid may serve as a guide. If the findings in this are all negative, there is every probability that the central nervous system is free. If the nests of spirochetes—which are probably responsible for the persisting Wassermann reaction—are located in other organs, the outlook is not so serious, for they can almost always be acted on here by intensive treatment. Neisser's idea is, thus, that it is indispensable to examine the spinal fluid in every case, but not often, merely to decide certain special questions. Each patient has to be warned that the lumbar puncture may possibly be followed by headache for several days, compelling him to stay in bed. This headache rarely occurs if the patient lies down at once after the puncture and keeps in this absolutely horizontal plane for twenty-four hours. Neisser injects now, directly after the puncture, 10 or 20 c.c. of the patient's own serum, salvarsanized or not, and this seems to be a more certain protection against headache.

32. **Constitutional Purpura.**—The first part of Frank's article was reviewed in these columns June 12, p. 2025. He here discusses the pathogenesis of the trouble, tracing it to a constitutional deficiency in blood platelets. Hence he prefers to call it by the more descriptive term "essential thrombopeny" instead of constitutional purpura or pseudohemophilia. In treatment, arsenic and sea or mountain climate are the main reliance with the use of an extract of blood platelets, locally or possibly intravenous, to arrest the hemorrhages. The extract of blood platelets contains the lacking thrombozyme and hastens coagulation. Intravenous injections of 5 or 10 c.c. of 10 per cent. salt solution are regarded by many as one of the best means to arrest internal hemorrhage. Frank adds that an ideal treatment is by intravenous injections of large amounts of normal blood plasma, rich in platelets. The blood of the donor (400 or 500 c.c.) is caught in a vessel covered with just enough leech extract to prevent coagulation (10 mg. Hirudin to 75 c.c. blood). After it has set on ice or been slowly centrifuged, the plasma is drawn and slowly infused into a vein. If the donor is not a blood relation, the plasma should be tested beforehand for a destructive action on the patient's blood corpuscles.

34 *Industrial Accidents from the Medical Standpoint. (Zum Unterricht in der Unfallmedizin.) F. de Quervain.

34. **Industrial Accidents from the Medical Standpoint.**—De Quervain regards it as great progress that in 1912 the authorities added a course on "accident medicine" to the medical curriculum in Switzerland. Hasty examinations and certificates made out in ignorance of the fundamental principles have often led to years of litigation that might easily have been avoided. The next step is to organize most wisely the course on industrial accident medicine to supplement the workman's compensation legislation. For this the present surgical clinics should be utilized for instruction in minor surgery and in the after-care of injuries of the fingers, for example. He emphasizes that there is no such thing as surgery especially for industrial accidents; the principles are the same for all, but we may speak of special arm and leg or "extremity surgery," and for this, as for all industrial accident medicine, practical rather than theoretical training is the main point.

36. **Improved Technic for Detection of Occult Blood in the Stools.**—Boas calls attention to the advantages of the simplified technic he is now using and has found much more sensitive than the benzidin and guaiac tests, while it is fully as reliable. An acetic acid-alcohol extract of the feces is made (5 drops glacial acetic acid to 15 or 20 gm. alcohol). Then 15 drops of the phenolphthalin reagent are dropped in a test tube, 5 or 6 drops of 3 per cent. hydrogen peroxid are added and 2 c.c. of absolute alcohol, and the whole is shaken up. Half of the above mentioned acetic acid-alcohol extract is poured into a filter-funnel and this is placed in the test tube so that the filtrate comes slowly into contact with the fluid in the test tube. If there is blood present, a pink or deep red ring forms at the junction of the two fluids. He purifies the commercial phenolphthalin by reduction with pulverized zinc in an alkaline solution. For this he shakes up 1 gm. of phenolphthalin in a solution of 25 gm. potassium hydroxid in 100 gm. distilled water. When thoroughly dissolved he heats the whole in an Erlenmeyer flask, adding metallic zinc until entirely decolored, which requires one or two hours. The fluid then is cooled, brought to the original volume and filtered. The fluid then is limpid, keeps several weeks unchanged and the colorless fluid shows no change of tint on addition of acetic acid, hydrogen peroxid or alcohol. Several hundred applications of this "phenolphthalin ring test" during the last few months have confirmed its superiority for examination of stools, but this technic cannot be used for stomach content. For this he prefers the guaiac test on an acetic-acid alcohol extract of the stomach content. In conclusion he reiterates the extreme importance of the discovery of occult blood in the stomach content as a sign of gastric or duodenal ulcer.

41. **The Laws Regulating Maternal and Fetal Syphilis.**—Trinchese's conclusions from his experience at a serologic laboratory at Berlin and analysis of the literature are to the effect that Colles' and Profeta's laws were based on mistaken premises and do not correspond to the facts, as there is no paternal transmission of syphilis, the fetus does not generate immunizing substances and the placenta does not permit passage of immunizing substances from the maternal to the fetal tissues. The earlier the fetus is infected, the more rapidly the syphilis runs the course of sepsis, killing the fetus within six weeks. Until about the eighth month the fetus does not generate immunizing substances, that is, its blood responds negatively to the Wassermann test even although its tissues may be swarming with spirochetes and the mother present a positive Wassermann. In the eighth and ninth months the fetus may begin to present a weak and inconstant Wassermann reaction. If the child becomes infected first during the last few weeks before birth, there may be no

clinical manifestations of the syphilis and no Wassermann reaction as the time has been too short for either to develop. These are the children that used to be supposed "immune"; they supply the material for the cases of tardy inherited syphilis. A syphilitic mother can have a child clinically free from syphilis and with a negative Wassermann; or the Wassermann may be positive; it may have symptoms of syphilis and a positive Wassermann; or it may have symptoms and a negative Wassermann. This sequence rises from the mildest to the severest type. The last mentioned—clinical manifestations of syphilis without any indications of a Wassermann reaction—generally proves fatal.

50 Causes of Death of Prominent Physicians of History. (Todesursachen bei namhaften Medizinern.) H. Vierordt. Commenced in No. 17.

43. **Wounds of Peripheral Nerves.**—Nonne remarks that soldiers afford more instructive data than the shifting inmates of public hospitals, so that the next year or so will probably add much to our knowledge in regard to injuries of peripheral nerves and effects of treatment. His experience with wounded soldiers has confirmed Charcot's saying that one must suspect hysteria everywhere. He reports a number of cases in which a wound was followed by paralysis but the behavior of the tendon reflexes in the paralyzed limb was normal, and the paralysis was soon cured by suggestion in hypnosis. In nearly every one of his cases of "grande hystérie" the true nature of the disturbance had not been recognized, and the diagnosis had been cerebral, spinal or neuritic paralysis, and time and effort had been wasted on futile measures. When hysteric contracture affects a limb that has been wounded, general anesthesia may be the only means to cut out the hysteric element from the clinical picture. In short, Nonne reiterates, hysteria very often fails to be recognized. This is particularly liable among the wounded as war hysteria takes predominantly the monosymptomatic and "local" (traumatic) form. He has operated in forty-five cases of wounds of peripheral nerves, and is convinced that a nerve that has been smoothly severed should be operated on early, as soon as the complicating lesions have healed. If there is doubt whether the nerve has been divided, wait six or eight weeks to see if function returns spontaneously. If not, operate. The after-care, exercise, etc., are of extreme importance.

44. **Typhus.**—Singer appealed to our exchange to solicit communications on this subject from hygienists, and five are published here from various leading hygienists. Uhlenhuth emphasizes the necessity for keeping the "clean" quarters separate from the infected quarters. It is impossible to be too careful here; no means should be omitted to keep vermin out of the clean part. Sticky substances, bird lime, etc., may render good services here. Persons who have had typhus should be selected for the care of typhus patients whenever possible.

46. **Epidemic Parotitis.**—This term, strictly speaking, does not apply to the two cases described, as the submaxillary and not the parotid glands were the ones involved. In each case the epididymis was also the seat of an inflammatory process instead of the usual orchitis. In both cases the pulse was very slow, only 56, and during fever only 84 in one case; in the other, 70 or 80 and 92.

49. **Retention of Placenta after Miscarriage.**—Walther discusses here merely the miscarriages occurring in the fifth and sixth months, with prolonged retention of the placenta. The danger of ascending infection and of hemorrhage in such cases does not seem to be appreciated by all physicians in its true importance, and he relates a series of five cases in which physicians had been content to wait for Nature to expel the placenta, and under this direful expectant treatment serious complications had developed. In one case sudden and serious hemorrhage recurred several times after an incomplete abortion; in others there were constant losses of blood. In the other cases there was putrid and septic infection. In two of the cases the physicians had made no attempt to empty the uterus; in the others repeated but futile attempts had been made.

Walther insists that during the fifth and sixth months the placenta should be expelled within two hours after the fetus, and the physician should see that this is done, with just as much care as at term. Physicians should study the relative proportions of fetus and placenta at different ages so as to recognize when part has been left behind. Figures are quoted showing that at the fifth month the placenta averages 10 by 12 cm., and is 1 or 1.5 cm. thick, and at the sixth month, 12 by 13 cm. and 1.75 to 2 cm. thick. These miscarriage cases are often particularly difficult to manage as the physician may not be called in until late, when all that came away has been disposed of. In order to stimulate the uterus to throw off the placenta, Walther advocates quinin, which, he says, has been crowded somewhat into the background by the hypophysis preparations. In miscarriage it works much more promptly than the latter, as he illustrates by two recent examples. In one the placenta had not separated by the twelfth hour but was promptly expelled spontaneously after two doses of 0.5 gm. quinin sulphate in one hour. He warns that ergot directly promotes retention.

If the Credé does not loosen the placenta, he repeats it under general anesthesia. If there is much hemorrhage the uterus can be manipulated by pressure from without and from two fingers in the posterior culdesac of the vagina. If the physician is called late in the case, Walther advises calling in an experienced consultant, as the removal of an undetached placenta with the cervical canal closed up requires great skill. The curet is dangerous, especially a small one, as it lifts part of the placenta and opens the vessels in that location beneath and from them the woman may bleed to death before the whole of the placenta has separated. Correct management of the retained placenta after a miscarriage during the second third of pregnancy is to dilate the cervix with a tent until the finger can be introduced; then loosen the placenta with the finger. If this proves impossible, introduce an abortion forceps to the lower pole of the placenta, or, as a last resort, a large, blunt, wide curet; abrupt dilatation of the cervix is dangerous.

62 *Wounds of the Skull. (Schädelschüsse.) H. Thiemann. Commenced in No. 17.

55. **Specificity of Protective Ferments.**—Jaffé and Pribram declare that although the nature of the protective ferments is still a mystery, yet the fact of their specificity seems now to be well established. They report further experimental work which confirmed that the digesting properties of the serum can be arrested by heating, but it can be activated again by adding fresh serum. Even when heated to 58 C. for forty-five minutes, rabbit protective ferments thus inactivated can have their digesting property restored by addition of fresh guinea-pig serum.

57. **Charcoal Treatment of Wounds.**—Lenz reports thirty cases in which charcoal was used, and with excellent effect, in treatment of suppurating wounds. They were first cleansed with hydrogen dioxid, then gently dabbed dry with gauze after which the surface was buried under a layer of charcoal blown on with an insufflator until the whole surface was black. The dressings were changed daily, hydrogen dioxid being used to rinse off the charcoal.

62. **Wounds of the Skull.**—Among the many points emphasized by Thiemann from his extensive experience is the advisability of refraining from anything more than cleansing the wound and dressing it, until the man reaches a well equipped hospital in the home zone. The way in which the gaps in the skull grow up is astonishing, as also the absence of deficit phenomena in many cases of extensive destruction of brain tissue. In one case none were evident although one-third of the right frontal brain had been shot away; in another most of the right half of the cerebellum had been destroyed, and in another large portions of the parietal lobe and central convolutions. The extent of the primary injury of the brain does not in itself contraindicate operative treatment.

63 Typhoid Among the Soldiers. (Zur Diagnostik und Therapie des Typhus im Felde.) F. Klemperer, W. Oettinger and F. Rosenthal.
64 *Autoserotherapy of Typhoid is Ineffectual. (Zur Behandlung des Typhus mit Eigenserum.) R. Meyer.
65 *Treatment of Exophthalmic Goiter. (Gesichtspunkte zur Behandlung des Morbus Basedowii.) W. Weiland.
66 *Aluminum Acetate in Alcohol Effectual in Smallpox. (Neue Methode der Blatternbehandlung.) F. Traeger.

64. **Inefficacy of Autoserotherapy of Typhoid.**—Meyer has given this method of treating typhoid a thorough trial, and reproduces here the curves of nine cases out of a much larger experience. He followed the technic which Widal and Königsfeld have used with much success, according to their published reports, but Meyer was unable to detect any benefit from it.

65. **Exophthalmic Goiter.**—Weiland remarks that men trained to think surgically are apt to regard exophthalmic goiter altogether too much from the surgical standpoint, and internists view it from the internal medicine standpoint, while men who have had much experience are liable to follow the method of treatment with which they have been most successful in the past, without due regard to whether the present case fits into the frame of the former cases. In the present article the experiences in Lüthje's service at Kiel for the last ten years are analyzed. They confirm the necessity, with internal measures, of supplementing general treatment both physical and psychical with a diet to influence the metabolic disturbances and specific treatment of the thyroid itself. Measures in all these directions are called for usually in every case, from the mildest thyrotoxicosis to the severest type of exophthalmic goiter.

Disturbance from perverted thyroid functioning develops very insidiously as a rule. At first there are symptoms of a general nervous disturbance; the temperature is normal unless there is an underlying tuberculosis. The proportion of patients restored to full earning capacity is larger under operative than under medical measures, but the latter perseveringly applied restore full earning capacity in a larger percentage than is generally realized. Still greater benefit can be realized if roentgenotherapy is used to supplement other measures, with or without an operation. Weiland states that he has never witnessed a case in which every one of the symptoms had entirely retrogressed under surgical or medical measures or both, but we are justified in calling the case cured when the patient feels strong and well, the heart behaves normally, and there is no further restlessness, tremor or abnormal sweating, and full earning capacity is restored.

The first thing in treatment is to ensure physical and mental respose; a few days in bed benefit in mild cases as much as a few weeks in the severer forms. This repose should not be disturbed by dietetic or other restrictions, but should be utilized to tranquilize the patient's mind and obtain his cooperation in the efforts for recovery. The treatment at this time should be the same as for nervous prostration or convalescence from any sickness except that sedatives may be required to overcome severe motor and psychic unrest. In the milder cases no drugs are needed unless a prescription seems to be called for, in which case valerian might be ordered. Arsenic is also useful, but he never gives iron The diarrhea or sweats disappear spontaneously as the general condition improves. For several years it has been the practice at Kiel to give sodium phosphate in every case of exophthalmic goiter, for reasons which Weiland enumerates, and it is regarded as an essential part of the treatment. It is given in daily doses of 3 or 4 gm. in a 10 per cent. solution. Digitalis is given only under the same indications and dosage as with organic disease of the heart.

The diet should be that of forced feeding, training the patient to masticate and striving to tempt his appetite, making special use of carbohydrates and fat, possibly supplemented with some pancreas preparation. It is not necessary to push the forced feeding to bring the weight up to normal. Local applications of cold and electricity may relieve the tormenting symptoms from vascular goiters. He has not had favorable results from organotherapy of exophthalmic goiter, but has been much impressed with the benefit from Roentgen exposures. They can be applied in all forms of exophthalmic goiter. He used hard tubes, of 3½ ma. with 16 x as the maximal dose, fractioned at two sittings with a few days' interval, repeating this for three or four months, with two and four weeks' intervals.

If the weight and strength keep running down and the heart functioning growing worse, an operation should be recommended without delay but otherwise not until after a thorough course of internal measures. For operative treatment, the objective symptoms form the criterion. Weiland in conclusion emphasizes that after operative treatment the patient requires medical oversight as much as after an operation for a gastric ulcer.

66. **Aluminum Acetate in Smallpox.**—Traeger has found extremely useful for all kinds of abscesses and glandular swellings the local application of aluminum acetate in alcohol. In a recent case of smallpox he applied it also and improvement was evident at once. The fever subsided and the pustules retrogressed, scarcely ever leaving a scar. This favorable experience was repeated in nine other cases during a small institutional visitation of smallpox. Most of the patients were children and these applications reduced the pain and itching so much that the children clamored for them. He used 50 parts of the aluminum acetate to 1,000 parts of alcohol rectificatus; cotton dipped in this was laid over the face and covered with oiled silk. The chest, abdomen and back were also dressed with the same mixture, alternately during three hours. Pitting seemed to be materially checked by this simple means.

Zeitschrift für Kinderheilkunde, Berlin

XII, Nos. 4-5 pp. 227-368. Last indexed March 27, p. 1117

69 *Associated Acquired and Congenital Diseases of the Skeleton. M. Segawa.
70 *Anomalous Roentgen Findings in Child's Thorax. T. Gött.
71 *Megacolon. (Die Therapie bei der Hirschsprungschen Krankheit.) O. Schneiderhohn.

69. **Congenital Plus Acquired Bone Disease.**—The child in the case reported in detail by Segawa was under constant observation from the day of birth to its death at eleven months. The parents were healthy except that the father is a hard drinker. The child presented typical congenital osteogenesis imperfecta, and on this became superposed both scorbutus and rachitis. The roentgenogram and the microscopic findings are compared with analogous cases in the literature. The work issues from Pirquet's service at Vienna and fills seventy pages.

70. **Anomalous Shadows in Child's Thorax.**—The puzzling Roentgen-ray findings were much alike in the two cases described but the affection was of an entirely different nature in each. In one there was an abscess from rupture of suppurating glands. In the other case there was a hard leukemic infiltration. Both processes had developed in the same tissues and in the same region in the mediastinum so that the shadows cast by both were alike. They differed from the shallow arc or rounding shadow, which Rach has described as typical of a spondylitic gravity abscess, in that the outline was longer and nearly straight. Possibly this straight instead of a curved outline of the shadow may aid in differentiation.

71. **Treatment of Megacolon.**—It is necessary in treatment to determine whether the cause of the distention of the colon is a spasm of the sphincter, or a congenitally normally large bowel, or whether it has enlarged from some mechanical bend or kink on account of abnormal length and the movability of the sigmoid flexure. Four cases are described; 2 were improved by internal measures alone and 2 by operative treatment. Adding these 4 to those found in the literature, Schneiderhöhn has compiled 358 cases of Hirschsprung's disease, and discusses the views of the various authors. The outcome is not known in 39 cases; 179 of the patients died, but the megacolon was not responsible for the death in 11 of these cases. In 110 cases a clinical cure was realized and great improvement in 24. No benefit was apparent in 9 cases. A cure was thus obtained in 30.7 per cent. of the available total, while the mortality was 43 per cent. Of the 151 treated by internal measures alone, only 38 were cured and 14 improved; 79 died, and the outcome is not known in 14 cases. In 6 no benefit was realized. Schneiderhöhn emphasizes that this unfavorable clinical record for internal measures—over half dying and only one-fourth cured—is due to inadequate or inappropriate measures or a too brief course of treatment or to the measures not being applied until irreparable lesions had been installed. Purgatives and enemas he ranks among the unsuitable measures, stating that he has found whole series of cases on record in which death followed almost at once after their application, and generally with the symptoms of acute colitis and perforation peritonitis. He cites some typical examples to illustrate this. Megacolon, he reiterates, is the manifestation of a mechanical closure of the intestinal tract which peristalsis is unable to overcome. Purgatives, enemas and coarse foods add to the distention and cause the bowel to work harder to get rid of its contents. This is liable to entail rupture at some eroded point. The parents often take the child home at the first sign of improvement, and it does not get the full course of treatment and proper aftercare. In the 143 operative cases, the mortality was 36 per cent.; the cures represent 46 per cent. Twelve different operative procedures were applied in the various cases, as he shows in tabulated form.

Analysis of all this material demonstrates that the mode of treatment must be selected for the individual case. We should not operate needlessly but neither should we delay too long with internal measures. They should be given a thorough trial first, combatting with sedatives any tendency to spasmodic contraction in any part of the bowel. If the contracted point is accessible it should be bloodlessly stretched. In other cases the bowel may be rinsed out, with ample drainage provided, reenforcing these measures with massage, electricity and a suitable diet. The above measures will often accomplish the cure if the patient comes under treatment early enough and if it is kept up systematically and long enough. Not only do the symptoms disappear, but the colon becomes reduced in size and the hypertrophied walls retrogress until the bowel functionates normally once more. Internal treatment is particularly liable to succeed in children. As they grow, the anatomic conditions approximate more and more closely to the normal condition in the adult. Of the 38 patients cured by internal measures alone, 31 were children; 12 others were improved. The proportion of children cured by operative measures is no higher than the general proportion of the cured. Of the 69 children operated on, 32 were cured and 26 died. Hence it is wise to hold back from operating on a child until internal measures have been given every chance, unless one's hand is forced by severe symptoms. When an operation is done it should be thorough and not leave conditions that will require further intervention. In a number of cases two operations were necessary; in 7, three; and in one case each, four, seven and eight operations were done. Colopexy or resection at two sittings gave the best results in the cases on record. These correspond best to the causal indications. The congenital enlargement or undue length of the loop may require resection if colopexy does not offer promise of a permanent cure.

76 *Somnambulism. (Zur Kasuistik des Noktambulismus.) J. Löwy.

76. **Somnambulism.**—Löwy thinks that there are possibly therapeutic hints in the case he reports: A young man with advanced mitral stenosis had severe congestion of the liver and kidneys, and ascites, compensation having entirely failed. At the slightest physical exertion there was arrhythmia and the much dilated heart was so incompetent that he was unable to take more than a few steps without help. The man in the next bed noticed about 1 a. m. one night that the young man's bed was empty and the nurse found at 3 a. m. that a window nearby was open. Suicide was suspected and the yard and the building were thoroughly searched in the dark, cold, rainy night but no trace of him could be found until 5 a. m., when he knocked on the outside of the window of another ward on the same floor and was taken in. He complained only of cold and fell asleep at once, and was unable to explain the occurrence when he roused. The window ledges were narrow and slippery and about one yard apart. It must have required considerable physical exertion to step from one to another, and yet for four hours the young man must have been circling the wall several stories above the ground. The pulse was found only transiently 20 beats above what it had been the day before, and the blood pressure had dropped from 115 to 110 mm. Hg: no other change could be detected. It is evident that in the somnambulistic state there are no nervous inhibitions, and hence the sum total of the work imposed on the heart by physical exertion is less. The physical exertion is made without any superfluous muscular movements, and hence makes less demands on the heart.

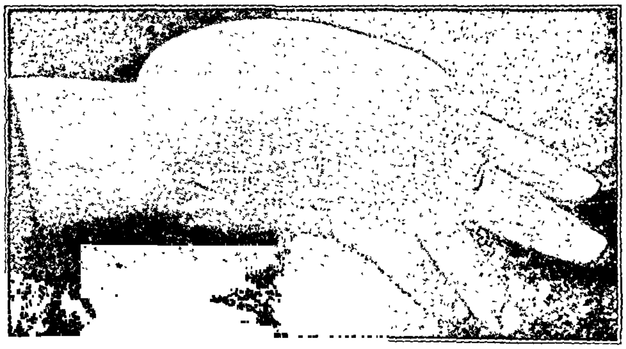
83 Indications and Contraindications for Salvarsan in Syphilitics with Other Diseases. (Arsenobenzolo nelle malattie mediche da sifilide.) T. Pontano. Commenced in No. 4.

79. **Serotherapy in Pernicious Anemia.**—Bartolotti has been impressed with the way in which the reds increased in numbers under the influence of antidiphtheria serum. This reaches its height the fourth or fifth day and then gradually declines, but never drops to its former figure. The effect is most striking when the number of reds is small to begin with. Antistreptococcus and antistaphylococcus serums have the same action but it is less pronounced than that of diphtheria antitoxin. He has also noticed that extracts of various organs have a notable influence in this line in severe secondary anemia. On the basis of these data he treated a woman of 38, with severe pernicious anemia rebellious to iron and arsenic, with antidiphtheria serum, giving four injections of 1,000 units each, with intervals of forty, sixteen and twenty-one days. A week after the first injection he commenced combined organotherapy, giving extract of spleen, spinal cord and blood, alone or combined; the daily dose was about 0.5 gm. of the extract, gradually increasing to 2.75 gm. a day and then tapering off. By the fourth day after the first injection of antitoxin the reds had increased from 823,750 to 1,618,000 and by the sixth week to 3,832,000 while the hemoglobin from 35 to 30 had risen to 90 per cent. Nearly six months after suspension of all treatment—the complete course having taken thirteen weeks—the hemoglobin was 95 per cent. and the reds numbered 5,084,000; the blood findings otherwise were also normal.



Flap taken from abdominal wall shares in obesity (Abstract 88).

82. **Action of Sugar on Kidney Functioning and on the Circulation.**—Crispolti has been studying in the clinic the application of the results of Lo Monaco's recent experimental research on the effect of sugar. He apparently demonstrated that small subcutaneous doses of sugar increase kidney functioning to a notable extent, while larger doses reduce the output of urine. The output is also reduced when the small doses are kept up for a long time. Crispolti injected intramuscularly into the buttocks 1 or 5 c.c. of a 100 per cent. solution of saccharose, and tabulates the findings in six persons with sound kidneys, the conditions of the tests about identical in all. The findings cover a period of thirty-two consecutive days in five cases and twenty days in the other case, and are tabulated under fourteen headings. The injections were made daily for a week or ten days and then suspended for equal periods. The findings show that small doses did not modify the blood pressure or the circulation, but that large doses, 5 c.c. of the 100 per cent. solution—increased the blood pressure and the pulse. The subjects also gained in weight on these large doses, showing that they have nutritional value as well. This explains Leo's finding that starving rabbits given a daily intravenous or subcutaneous injection of 1 gm. glucose survived five days longer than the controls. Crispolti found also that the sugar solution had a marked effect on the action of the kidneys, small doses stimulating and the 5 c.c. doses checking kidney functioning. Not only the total output of urine was reduced, but the proportion of urea and chlorids was also reduced. The patients were very thirsty and drank much more water than usual, and they complained of not feeling so well; they lost appetite and some had headache and nausea under the large doses. He thinks the reduced output of urine and of urea, etc., amply explains these vague disturbances under the large doses. On the other hand, diuresis was materially promoted by the small 1 c.c. doses, and the proportion of urea and chlorids also increased. With the small doses there were no disturbances, no excessive thirst, and the mouth was moist; with the large doses the mouth felt parched.

Sugar in small doses seems to dilate the blood vessels while in large doses it has a constricting action on them. This explains the cases in which hemorrhage has been arrested by injection of sugar. It also offers an explanation of the inhibiting action of large doses on diuresis; the vessels in the kidneys of course share in the general constriction. The data thus presented suggest that small doses of sugar to promote diuresis are indicated in all conditions of oliguria from various causes. Large doses, on the other hand, will prove useful to reduce polyuria in diabetes or nervous polyuria if the blood pressure is *not overhigh to start with.* While the large doses are being taken, the diet should be mostly liquid; this not only tends to prevent harm from the retention that follows the large doses, but it facilitates diuresis.

WORK OF THE AMERICAN MEDICAL ASSOCIATION *

WILLIAM L. RODMAN, M.D.
President of the American Medical Association
PHILADELPHIA

In assuming the presidency of the largest and most important medical organization in the world, and at the time of its greatest achievements, I am overcome with humility and a consciousness of my own limitations. Profoundly grateful for so signal and unmerited an honor, I shall ask that the same partiality which placed your standard in my hands strengthen and support me until I shall have transferred it, unsullied and undimmed, into the hands of my successor.

With your help I may succeed; without it, failure is certain; therefore, grant it me in unstinted measure.

As the splendid work of the Association, carried on by its officers and several councils, has not been reveiwed by my immediate predecessors, it would seem eminently fitting that I should, at this time, attempt a retrospect of some of its most noteworthy achievements, and incidentally point out how, with your cooperation, other equally desirable results may reasonably and certainly be attained.

THE AMERICAN COLLEGE OF SURGEONS

As the American Medical Association always stands for altruism and noble endeavor, it is my first duty, as well as my great pleasure, to congratulate most heartily the officers, board of regents and fellows upon the auspicious beginning of the American College of Surgeons, its achievements and its splendid aspirations. It has already, in its brief existence, accomplished much in elevating the general tone and level of American surgery, and met all reasonable expectations of its sponsors. The college was organized to fill a distinct need, and its aims and purposes were well presented by its president, Dr. J. M. T. Finney, at the inaugural meeting in Chicago, in November, 1913, in an address which was notable for its ability, sincerity and lofty character. With a rare and keen discrimination, equaled only by the courage shown, he pointed out the weaknesses in our armor, and the professional obligation of all to overcome them. I cannot do better than quote some of his forceful words, and, further, to express the hope that every member of the profession, in or out of the college, will read and read again the entire address:

> The aim of this new organization and the reason for its existence lie in its disinterested and unselfish efforts to elevate the standards of the profession, moral as well as intellectual, to foster research, to educate the public up to the idea that there is a difference between the honest, conscientious, well-trained surgeon and the purely commercial operator, the charlatan and the quack; furthermore, that the term "surgeon" means something more than a suave manner, a glib tongue, a private hospital, a press agent, and the all too easily acquired diploma. The standardization of surgery is absolutely essential to guard the public against such as these, as well as to preserve the honor of the guild itself. So far as the public is concerned, it is necessary to protect it from the wolves in sheep's clothing, from those who would prostitute their high office for the purpose of gain; from the ignorant and the untrained; from those who by reason of the lack of surgical judgment and skill are incompetent. That such are present in considerable numbers in our profession, and that they continue to ply their nefarious trade in every community of any size, with reckless disregard of the consequences, unfortunately cannot be denied. Are we to sit idly by while the fair name and fame of our profession are being dishonored and defiled? Is there nothing that we can do to protect the public and ourselves? Our presence here this evening is an answer to these questions. The American College of Surgeons has been called into being as an active, vigorous, virile protest upon the part of the profession itself against this unhappy state of affairs.[1]

No one who impartially reviews the work of the college, conducted as it has been by officers and a board of regents of the highest personal and professional standing, can withhold from them a large measure of praise for unselfishness, devotion to the cause, and a very evident intention to be true to the highest ideals of the profession.

In every community men are operating who have no right to take human life into their hands. This does not apply to the general practitioner who, in an emergency, and to the best of his ability, operates in an attempt to save life, but to those who, for gain, undertake that which should be done only by the skilful surgeon. Surgery is a special science, extrahazardous in its nature, and hence the public has a right to demand of the surgeon the very highest physical, mental and moral equipment.

The positive stand the college has taken on fee-splitting alone more than justifies its existence. This evil has become intolerable, and a wave of protest is rising throughout the land which should, and we believe will, overwhelm the offenders. Reform is bound to come, and the public will surely take the initiative if we do not. In some states the legislatures have already enacted laws constituting fee-splitting a crime. But it is most undesirable that our problems and shame should be corrected by legislators who imperfectly understand the real conditions. Let us at once apply the axe to the root, make this nefarious practice impossible, drive from the surgical temple those who defile it, and let their names and methods be anathema maranatha. If there be those within the ranks of the college who are at this time tainted with commercialism, it was not so intended by the board of regents, and they will make short shrift of any one caught *flagrante delicto*. I hold no brief for the board of regents, but am acquainted with every one of its members, and am satisfied that the honor of American surgery is safe in their hands. Undoubtedly mistakes have been, and others will be, made. But shall we expect human prescience to do that which Christ Himself did not do? Did He not in selecting His disciples choose Thomas who doubted, Peter who denied, and Judas who betrayed Him?

---

* President's address before the American Medical Association at the Sixty-Sixth Annual Session, San Francisco, June 22, 1915.

COUNCIL ON HEALTH AND PUBLIC INSTRUCTION

The Council on Health and Public Instruction continues to investigate health conditions, to educate the public and to foster a sentiment that will force the enactment of health laws. We are better prepared today to prevent disease and to save life than ever before; but we need the confidence and intelligent cooperation of the people before the work can be satisfactorily accomplished.

The Council is in touch with the newspapers, and since the Press Bureau was established three years ago, has issued 164 bulletins for publication in 4,900 newspapers. These bulletins are made up of extracts and abstracts of editorials and original articles from The Journal, with occasional articles on popular health topics, contributed by prominent members of our Association, but published without signatures.

Popular write-ups on medical subjects are too often but garbled statements of medical facts. Yet the daily press wishes, and has a right, to publish what the people want to read. In Kings County, N. Y., a publicity committee has cooperated with newspaper editors in working out a plan for getting truthful reports of interviews on medical topics. This scheme has worked so admirably that the Judicial Council recommended to the House of Delegates the formation of such a publicity committee in every county medical society in the country.

Another plan of the Council is to unite all of the public health organizations into a national league. With this in view, it has suggested that the various public health organizations hold their 1916 annual meetings at the same time and place. Special societies, such as those for the study of tuberculosis, cancer, infant mortality, etc., might be made sections of this national league, which would be a great advantage to them.

The Bureau of Literature has circulated pamphlets on health topics, notably on cancer, which at this time is being given great attention, not only by our Association, but by the American Society for the Control of Cancer, by a cancer committee appointed by the Clinical Congress of Surgeons of North America, by the Cancer Commission of Harvard University, and by state and municipal commissions as well, all working to the same end, namely, the enlightenment of the public as to the early symptoms of cancer, the necessity for prompt surgical intervention and the danger of running after false gods.

Several speakers connected with this bureau have told me of the large and interested lay audiences they have addressed in different parts of the country, and I myself have had a similar experience in the states of Maryland, Virginia, North Carolina, Ohio, Missouri, Illinois, Minnesota, New Jersey and Pennsylvania. I have also been assured by local physicians in the cities and towns visited by such lecturers on cancer that the results have been most encouraging, and in many instances have led to early operation where, without such knowledge, the patients might possibly not have been operated on at all. I believe that the Association has done, and can do, no better work. In addition to the agencies already named, the federal government, through the director of the census, announces a new departure which should be welcomed. When the 1914 returns come in from the United States registration area, they will be made the subject of a special monograph on cancer. The deaths will be classified under some thirty headings, instead of seven as heretofore, and according to the region or organ affected, which is the arrangement followed in the standard reports of the registrar general of England and Wales. While not germane to the cancer question, it is of interest to note that the government Public Health Service also has undertaken a new work in beginning a sanitary investigation of navigable waters, thus far confined to the Potomac, Ohio, the shores of the Atlantic and the Gulf. This promises to be of vast interest and benefit to the entire country.

Many committees have done admirable work, notably the Committee on Resuscitation from Electric Shock, who have issued a chart and booklet for use in electric lighting plants which is considered authoritative all over the world; also the Committee on Resuscitation from Mine Gases, a report of whose work has been issued by the federal government.

The Joint Committee with the National Educational Association has been engaged in a fruitful study of health problems in education which will give an impetus to sanitation in rural schools, hitherto much neglected.

The activities of the Medicolegal Bureau are still in their incipiency, and it must be admitted that on the question of public health legislation the profession is still at variance. Efforts have been made, for nearly half a century, to secure the passage of laws regulating the practice of medicine in the different states, yet we fail to agree on the most essential requirements. The Association is, however, now making a more scientific study of medicolegal questions, and has issued two pamphlets dealing with this phase of its work. Nothing, however, could be more unwise or undesirable than hasty or ill-considered legislative experiments.

PROPAGANDA DEPARTMENT AND THE COUNCIL ON PHARMACY AND CHEMISTRY

The Propaganda Department reports an increasing public interest in the matter of "patent medicine" frauds, and has issued more than thirty educational posters as well as lantern slides for popular lectures on this subject. Boards of health, clubs and newspapers are alike active in disseminating information to the public.

The aims of the Council and what it has accomplished have made an impression upon the medical profession of both England and Germany, and in the latter country an association with similar functions has been formed.

Naturally the work of the Council has aroused much antagonism on the part of pharmaceutic manufacturers and those journals which make advertising a specialty, and some drug firms have threatened the Council with legal proceedings if it published anything concerning their products. Others have already begun legal action which is being vigorously resisted by the Board of Trustees. But it is gratifying to note that other firms whose preparations are really new and of therapeutic value have voluntarily submitted them to the Council for examination and endorsement. Drugs are accepted only after most careful investigation.

The Association now has in its laboratory three chemists who give their whole time to the analysis of medicines. The Council has attempted to distinguish between medicines good and bad. In addition to New and Nonofficial Remedies describing proprietary and new drugs which are deemed worth the consideration of physicians, it has published "Useful Drugs," which contains the really valuable drugs in our materia medica. This a number of the best schools now use as a textbook. Its labors, too, have materially influenced the teaching of materia medica and therapeutics. It remains, however, for the profession to set its ban on all proprietary medicines, if the only information concerning them comes from those who manufacture and sell them.

A few newspapers submit their medical advertisements to the Propaganda Department for its opinion before publishing them. Would that the so-called independent medical journals might follow their example, and seek an opinion before advertising outrageously fraudulent nostrums in their columns.

The medical profession should realize the inconsistency of its Council working to eliminate these products and some of its journals doing their best to perpetuate them. It is absurd for us to fight self-medication on the one hand and encourage it on the other. Can we not by concerted action either stop these obnoxious advertisements or refuse to countenance the journals that carry them?

COUNCIL ON MEDICAL EDUCATION

The Council on Medical Education was established in 1904. Conditions demanded its creation, as other agencies had proved inadequate to meet a situation which had become intolerable. The moral influence of this great Association was necessary to quicken and give vital force to what had long been good intentions or ambitious dreams on the part of other and smaller organizations.

Its work has more than justified its existence; for it has, in a decade, accomplished more in the way of regulating and elevating medical education than had been done in a century; and it has been able to do this without the slightest legal power, but solely by reason of the righteousness of its cause, the high character of its members, and the wide publicity given its recommendations and acts in a journal which goes approximately to 70,000 medical men weekly. No institution could resist, much less defy, the official acts of such a body.

The profession has given the Council most cordial support, and it cannot be said that schools have been irresponsive. Indeed, when one considers the chaotic state of medical education in the United States in 1904, and then views the situation as it is today, there is cause for felicitation all around — to the Council, to the profession of the country, and to medical institutions — for so happy a consummation could not have been reached without the hearty cooperation of all.

Truth to tell, there are outside influences which have been most helpful in this beneficent work, and to them all due credit should be given ungrudgingly. The Association of American Medical Colleges, the Federation of State Medical Boards, the American Academy of Medicine and the Carnegie Foundation have at all times cooperated cheerfully, zealously and effectively. But, after all, is it not to the greater credit of the Council that it has been able, largely through the tactfulness and diplomacy of its chairman, to make use of and coordinate so many forces for good, which, while working separately, as they hitherto had done, had oftentimes, though inadvertently, pulled apart instead of together? No one who has attended the annual meetings of the Council, Federation of State Medical Boards, and College Association, held on consecutive days, in the same hall, the members of each body having the privilege of debate in all, could fail to be impressed with the admirable team work thus far displayed. To have united these bodies for effectiveness called for the ability of a wise general, and to weld and hold them together may require the genius of a field marshal.

If mutuality is to be the watchword of all, the structure must, and will be enduring; but if one body insists upon conditions and standards which do not commend themselves as both reasonable and attainable throughout the whole country, there is danger of retrogression. We go either forward or backward; the former is usually difficult, requires time, and those who are to be successful must keep ever in mind the admonition, "They stumble that run fast."

When the Council was organized in 1904, it published, as an ideal standard to which it would gradually approach, the following:

> (*a*) Preliminary education sufficient to enable the candidate to enter our recognized universities, the passing upon such qualifications by the state authorities.
>
> (*b*) A five-year medical course, the first year of which should be devoted to physics, chemistry and biology, and such arrangements should be made that this year could be taken either in a school of liberal arts or in the medical school. Of the four years in pure medical work, the first two should be spent in laboratories of anatomy, physiology, pathology, pharmacology, etc., and the last two in close contact with patients in dispensaries and hospitals in the study of medicine, surgery, obstetrics and the specialties.
>
> (*c*) A sixth year as an intern in a hospital or dispensary should then complete the medical course.

This goal has been reached, at least on paper; the ranks have been thinned, as more than a third of the schools are now *hors du combat,* and it is expedient to mark time for a while, and give those institutions which have approached the firing line at double-quick speed a chance to catch their breath.

There are many reasons why this should be done. In the first place, the standard is now as high as it should be for *all* of the schools of the entire country. An irreducible minimum has been reached, and should be honestly enforced — that is, as soon as it can be. There is, of course, no limit to a maximum that any highly endowed and exceptionally circumstanced institution may adopt for itself.

Second, the present standard of the Council (four years in an accredited high school, one year in the basic sciences of chemistry, physics and biology) is on a parity with that of Canada and Great Britain, and with European countries. What reason have we to establish a cultural standard in medicine higher than that imposed by older countries?

Third, medicine is not a thing apart, but only a link in the educational chain, and should be based upon and correlated with the secondary schools, colleges and universities of the country. Professional education, in medicine at least, has advanced much faster than our general educational system has done. Would it not be logical, henceforth, to direct our efforts toward stimulating progress in secondary education until it shall have caught up?

To make my meaning clear: We demand a four-year high school diploma, and, in addition, one year in biology, chemistry and physics of every matriculant in medicine; and this, notwithstanding the fact that many of the states are poorly equipped with *good* four-year public high schools, and that some, though having recently acquired them, are as yet without graduates. But the very states without such secondary schools, upon which we depend for the necessary cultural knowledge as a prerequisite to the study of medicine, have from one to three medical schools drawing nearly all of their students from their own state. No one knows this better, nor has any one expressed it more clearly, than did Dr. Pritchett when he said:

> To enforce honestly a four-year high school requirement would call for great firmness and self-denial on the part of the medical schools [in the South]; but to require on top of this a year of college including the sciences and a modern language is to inaugurate anew a régime of compromises and makeshifts, and to substitute an imitation of education for the genuine thing.

Furthermore, the second requirement, one year in the sciences, is no better, if, indeed, so well complied with. The high schools, colleges and universities by no means agree as to the character, scope and extent of such course, and when it should be given. At this moment their differences could not be greater or confusion worse confounded.

Fourth, it is paramount that a man complete his professional training and begin to practice by the time he reaches 25. This must appeal to every one who views the situation from a practical standpoint. To be a nonproducer, a dependent upon some one else, at an age when men can be both productive and independent, is abhorrent to the American mind, as we are sensitive upon this point and a people of action rather than doctrinaires. Therefore, the Council should keep ever before it this essential fact, and other less important requirements should weigh as nothing against it. Furthermore, there is a way to bring this about without in any way curtailing either the secondary or professional training one must have. The fault at this time is unquestionably with the secondary, and not the professional end of it. We have agreed that a course in biology, chemistry and physics is a prerequisite to the study of medicine, but we do not agree at all as to where, how and when such a course should be given. At this time it is given in the high schools, in the colleges and in the universities, and, judging from the very recent report of the committee appointed by the Association of American Medical Colleges to investigate the subject, is taught as indifferently in one place as another.

In order to meet this condition, medical schools not connected with universities, and some that are, have been compelled to take over this work so that it may be properly correlated with medicine. It should be given, however, by a separate and distinct corps of teachers, and entirely apart from the work of medical students. This system, while educationally unsound, as we must admit, became a necessity because of the unsatisfactory courses given by the various secondary schools, colleges and universities throughout the country, and, moreover, the seeming unwillingness on the part of their representatives to modify their courses in any way, either for the convenience or benefit of those intending to study medicine subsequently. And yet, these same presidents, deans and other representatives of colleges and universities seriously advise us to add another year of university work, so that sufficient science shall have been taught the prospective medical student. Why should such a demand be made only upon American medical students? No other country makes it; why then should we? To spend an unnecessary year of one's life in obtaining cultural knowledge that is, to say the most, of questionable and uncertain value to him in his profession, is worse than a crime — it is a blunder. The literary colleges must at least improve their laboratories and tuition, so far as the sciences are concerned, before they can reasonably ask that one relatively fruitless year be passed within their walls; to double the dose would certainly be a serious handicap to the student and might be fatal to our educational system. The committee appointed by the Association of American Medical Colleges has this to say in its report:

> We are forced to the conclusion that the literary colleges over the country are not giving the science subjects demanded in our schedule in their first year's curricula, and, apparently, in many instances are not giving biology and physics as regular work for a bachelor's degree.[2]

If we add to this testimony that of President Lowell of Harvard and others who have read papers at the several conferences referred to, it is perfectly clear that there is no uniformity of practice or thought among the officials of colleges and universities, so far as the scientific course is concerned. Therefore, for the present at least, it must be taught largely by the medical schools, as has long been the custom in England, where the results are most satisfactory; or there must be as has been suggested by distinguished educators, a rearrangement of the curricula of high schools, so that they will embrace a course in the sciences which will be acceptable to medical schools. This, I believe, is the very best solution of the problem, as there is no good reason why a first-class high school should not give a boy such instruction whether he intends to study medicine or not. Many of the high schools do this now, and all might be induced to make the necessary change reasonably soon. In a recent conversation with the principal of the Central High School of Philadelphia and the head of the department of science, both expressed the opinion that boys leaving the high school should be fully prepared to begin the study of medicine. Both men are entirely familiar with our modern requirements, as they have kept in close touch with the situation at all times. Professor Keller, for many years head of the science department, has been kind enough to give me, in addition, his opinion, in a letter from which I am authorized to quote. He says:

> We are satisfied that the instruction now given in our scientific course fully meets the present actual requirements for entrance to the medical schools. The work includes a comprehensive course of instruction in science, including biology, zoology, physiology, physics and chemistry, as well as in two languages, either Latin and German, or French and German.

---

[2] The members of the committee making this report are all connected with universities.

> We can see no reason why the present requirements in biology, physics and chemistry should not be covered by the instruction given in any first-class high school, such as we have in the larger cities.

The reasons for giving this instruction in high schools are many. First, boys from 15 to 19 are at the very time of life when they are more interested in such a course than they would be later on at college or university, when they will, perhaps, have chosen their future vocations and wish to prepare for them specifically. Second, education is naturally a function of the state, and this is being realized more and more all the time. One has only to consult the reports of the commissioner of education at Washington to be convinced of the marvelous changes for the better wrought in a decade. In 1901 there were 8,210 secondary schools with 649,951 students, whereas in 1911 there were 13,268 such schools with 1,246,827 students.

Mr. Claxton, commissioner of education, suggests that the twelve years of elementary and high school, now grouped into eight years of primary and grammar school and four years of high school, be rearranged, making the course six years in each. Taking the seventh and eighth years as part of the high school makes it easy to begin departmental teaching in these grades, and to adopt the methods of teaching and discipline to the changing demands of the children. It also makes it possible to begin vocational education two years earlier than is now the case, which all must think desirable. Virtually nothing is lost in the primary school by such an arrangement, as teachers are generally agreed that the time spent in the seventh and eighth grades is nearly always, under the present plan, a period of marking time.

> High schools change with surprising swiftness, even in the older states. What was last year a registered three-year high school in New York often becomes this year a registered four-year high school. During the past decade a steady stiffening of the requirements for admission has occurred. Only the better high schools have been able to keep pace with these changes and to meet fully these requirements. The whole system of secondary education of a state may undergo in half a decade a thorough reorganization and uplift; the State of Virginia offers an example.[3]

I quote again from Commissioner Claxton:[4]

> Not only must the courses of instruction in all public schools be varied and differentiated to meet the varying needs of all the children of all the people, they must also be so adjusted as to give the information and training necessary for intelligent and successful employment in all standard occupations. Whatever is needed to be done for the welfare of society in city or state should be taught in the public schools, unless it can be taught elsewhere better and more economically.
>
> Whatever may be the solution of the problem of vocational education, it is quite clear that two things should be held firmly in mind: (1) that all education is one thing and not many, and that vocational schools are an integral part of our common school system; that whatever may be the trade by which one makes a living, humanity and citizenship, with all their requirements, are common to all, and must be considered in the education of all individuals and classes.

In the state of Pennsylvania there were but 193 four-year high schools in 1904, whereas there are 353 reported in 1914 (of these, forty-three are in cities and 310 in counties). There are still more schools giving three and two year courses, it is true (383 of the former and 134 of the latter); but if the rapid evolution of the past decade continues, there will very soon be more high schools giving a four-year course than schools of lower grade.

Now, while high schools are undergoing such evolutionary changes, is the propitious time to make an appeal to them to arrange their curricula so as to include a liberal science course. This appeal should have additional weight because they are public institutions maintained for the advantage of all; whereas colleges and universities, being largely private corporations, are managed to suit themselves and their officers, and would naturally be less responsive to outside requests or influences. The advantages would be palpable and direct, mutually beneficial to state, municipality, secondary, higher and professional education. The state and municipality owe, and can perform, no higher duty than to furnish youths with the very best educational advantages, as all that they give in this way is thrice repaid in a quickened, higher and better citizenship. Perhaps the very best and most wholesome law which a state can enact is that making education compulsory, thereby, to a certain extent, taking the control of a child from its parents. If this right is both assumed and exercised, it should be carried out conscientiously, wisely and thoroughly, and the states, domestic and foreign, that have measured up to this obligation have secured results which have placed them far and away ahead of those which have not. In no other way can we explain the satisfactory state of medical, as well as other branches of professional education in Germany and France, for instance. There professional education is considered, as it should be, a part of a general educational system, and hence is built upon a solid foundation. The thoroughness of the German secondary school system is most admirable, and should be imitated by other countries. The French, however, have better solved the question of premedical education, which is, at the present time, the most important question awaiting solution in America. After leaving the lycée with a baccalaureate, one must, before beginning the study of medicine, take a scientific course for one year, which includes physics, chemistry and natural history. It is designated as the P. C. N. course. It is given under academic auspices, and not by the medical schools—a practice educationally sound beyond question—but the course is objected to by the teachers of medicine as being too general in its scope and not sufficiently correlated with medicine. It is, nevertheless, thorough, embracing lectures and demonstrations in the morning, and active, practical work in well-equipped laboratories in the afternoon.

In England the same distrust of college and secondary school training in the fundamental sciences, upon which medicine rests, has always been shown, and to such an extent that the Conjoint Board of London, representing the Royal Colleges of Medicine and Surgery, refuses to recognize and give full credit for any such course taken outside of a medical school. Subject, but not time, credit is given. A student from such institutions must spend at least six months in the first year of a medical school reviewing what he has already had, and going further in the basic sciences before he can enter the second year of a five-year course in medicine.[5] This action is made necessary by the rudimentary state of public, or what they call board school, education in England, and the unevenness of scientific instruction elsewhere than in medical colleges. It is thought to be the best possible solution of the problem for that country, at this time, by an able, experienced and impartial teacher who is thoroughly acquainted with educational matters throughout the world, and who is, moreover, an enthusiastic advocate of the French system wherever it is practicable.[6] So, even if it be maintained that many of the high schools will not, or cannot, give an entirely satisfactory course in the sciences, their students beginning medicine can be given subject but not time credit, as is done in England, by our medical schools. I am of opinion that the English plan, which requires that at least six months of the science course be repeated, has much to recommend it and gives better practical results than the French system. When a boy takes his scientific course in a medical school, he is already pursuing what is to be his life work, he associates with medical students, occasionally attends, and is, perhaps, inspired by, a clinic, and his work of the first year is properly correlated with that of the second; moreover, and this is of the utmost importance, he is away from the many distractions inseparable from the first year of college life, when it is not expected that he take matters too seriously, but drift with the current.

[3] Babcock, Kendric Charles: Bull. 29, U. S. Bureau of Education, 1913.

[4] Report of Commissioner of Education.

[5] Frederick G. Hallett, Secretary, Conjoint Board, London.

In the medical school it is intensive study; in the college extensive study. I believe intensive work is better for the professional man, whereas a more diversified and widely distributed course is better for the man of letters.

The suggestion of Dr. Pritchett and Mr. Flexner that the secondary schools of Germany should include a satisfactory course in the sciences is certainly, I think, as applicable to our public schools.[7] Commissioner Claxton has shown it to be not only desirable, but also feasible in the United States, where changes are being made so rapidly in our secondary schools. Therefore, the present is the opportune time to bridge the gap between the secondary and vocational school by bettering the former and permitting a youth to begin medicine, law, engineering or other vocation before he is 20. It will then be quite possible for him to have graduated from a medical school and to have had a year's service in a hospital by the time he is 25. Then, and then only, in my opinion, will we get the type of men for whom there is a demand in the profession. To require, as medical schools do today, that part of one's preliminary education shall be in a high school, where there is confessedly no average standard for all of the states, and another part in a college or university where no greater uniformity is to be found, is, to say the least, an anachronism. We are a young nation with no hampering restrictions and traditions to fetter and hold us back when the very life of our educational system is at stake. Either the high school system should be changed, as urged by Commissioner Claxton, so that the four-year course will embrace all of the English, mathematics, sciences and languages necessary for professional enrolment, or paper credentials, which are now of relatively little value, should be given up altogether, and men accepted as medical students only after passing the necessary entrance examination.

Practically all medical teachers agree that the greatest defect with students is, and always has been, the lack of an adequate knowledge of English. Mathematics, the sciences and languages are of great importance, unquestionably; but to understand, to speak and to write English correctly is of far greater importance, and should be insisted upon as paramount. It was undoubtedly wise for the Council to omit German and French as a requirement after 1914. In lieu of them, it should strenuously insist on a more thorough preparation of students in English, and suggest that it take the place of German, which was formerly advocated by the Council, is still being taught by many schools in the premedical year, and is insisted upon by the Association of Colleges. A student can learn but little of any language, of which he has known nothing previously, in one year; yet the same time given to the study of English, and the necessary emphasis put upon it at the very beginning of his professional career, would be most fruitful. Appearance, address and correct use of English must always be among a physician's best professional assets, and to be indifferent concerning any of them certainly does not make for success.

In 1903, at its annual meeting in New Orleans, the Association of American Medical Colleges enacted into law a recommendation which had been made the year previous by President Vaughan to the effect that all matriculants in medicine should have a four-year high school diploma. A committee had been appointed at the meeting in Saratoga, and reported formally on the recommendation at New Orleans.

I had then, as now, the distinguished honor of succeeding Dr. Vaughan as president, and used what personal and official influence I could summon to put into effect his recommendation, notwithstanding the fact that it was strenuously opposed by many of my best friends and the two faculties of which I was then a member. As there were only about one third of the number of high schools in 1903 that we have now, and most of them gave one, two and three year courses, and but few a four year course, it was thought best to make the new requirement effective after July 1, 1905, and to give the student the option of an examination in lieu of a satisfactory diploma. This postponement also gave schools time to discharge all outstanding obligations to their students who had matriculated under the former standard. Some of the present difficulties were foreseen, but there was not, and should never be, the slightest sectional discrimination in an organization that is national in scope. This may be proper on the part of states, but the Association of American Medical Colleges and the American Medical Association should legislate, and have always legislated for the entire country.

There is but little doubt that the action taken by the College Association in 1903, and by the American Medical Association since the creation of its Council on Medical Education in 1904, has done much to stimulate the high school system all over the country, improving those schools which did exist, and causing states without adequate high schools to establish them. The medical profession has always exercised a wide influence on our common school system, as thousands of its members serve on school boards throughout the country, have intimate contact with educators, and can exert a wholesome influence upon them. Now is the accepted time to do it, for there are evidences of unrest everywhere. I know that it exists in Philadelphia, and that the adoption of the suggestion of Commissioner Claxton for junior and senior high schools is now being actively agitated in that city.

It is clearly the duty of the Council on Education to have, and even to publish, a list of acceptable and unacceptable medical schools; but I agree with the position taken by Dr. Pritchett, in his paper at the February conference in Chicago, that the simpler the classification the better, as fewer mistakes will be made and, therefore, heartier support accorded by all. Nice discriminations between wholly acceptable schools are unnecessary, serve no good purpose, will naturally be resented, and may lessen the usefulness of the Council. There is always danger of overdoing a good thing. For example, all will agree that the railroads of the country formerly needed regulation by state and federal government, so flagrant had been their offenses and shortcomings. But nearly everybody, certainly a majority, now think that zealousness in the best of causes went too far, and resulted in injury to the railroads, the country and the people. Hence the present reaction and undoing of much that was unwisely done.

---

[6] Flexner, Abraham: Carnegie Report.
[7] Carnegie Foundation, Medical Education in Europe, 1912.

Therefore, the Council abolished "A plus" from its classification. It is proper and feasible to distinguish between schools which are acceptable and those which are not. The former have the necessary all-time teachers, equipment and hospital facilities, the latter are wanting in all of them to a greater or less extent; hence there can be no honest and intelligent difference of opinion concerning them. But, when the Council undertakes to discriminate between high grade schools, mistakes certainly will be made, as Dr. Pritchett so forcibly pointed out; for men would be more than human if they did not use all honorable means to secure the highest rating for their schools, and resent that which seems a work of supererogation, needlessly discriminatory, and inviting criticism and opposition. But while I am very clear as to both the wisdom and expediency of the present classification, I am also of opinion that it is the duty of the Council to give full credit to schools — and to make it equally prominent in its reports — which maintain a different standard from its own, be it higher or lower; and, further, to express an opinion, not only as to the ability of a school to fulfil its pledges, but also if it is consistently doing so. Standards are worse than useless if they are not both honestly and fearlessly enforced, whether the offender be strong or weak. Let others, as the prospective medical students who are most concerned, know exactly what the country offers in an educational way, and precisely where they can get it — not where it is promised. Every one knows that the catalogues and other announcements emanating from schools cannot be absolutely relied upon, as they are oftentimes the specious plea of the advocate and partisan and, if accepted at their face value by prospective students of medicine, will prove in the end both disappointing and illusory. One will hardly go to a doting parent for an unbiased opinion as to the ability, beauty and virtues of a child, nor will one seek opinion concerning a pastor from one of his devoted parishioners. It is about as wise to expect all deans who write medical and other prospectuses to spend their time in criticizing their own institutions.

At the meeting of the Council, Dec. 28, 1914, a suggestion was made, to the effect that, in addition to and following the official classification, the Council should enumerate on a separate page all those schools which require a diploma before one can begin therein the study of medicine; on another page those schools which require two or more years of college work before matriculation in medicine; on still another page those schools which require one year of collegiate work, and, on a final page, those schools which require, in addition to a five-year medical course, a sixth year as intern in an acceptable hospital. The representative of the Federation of State Medical Boards, who was present, said that this arrangement would greatly facilitate their work. I again endorse the proposition, and hope to see it become operative.

A committee, of which President Vaughan is chairman, was appointed by the Council to report a plan by which clinical teaching can be made more effective and practical. On this committee are ten of the ablest and most experienced teachers in the country, and their final report, whatever it may be, must have great influence toward controlling clinical teaching in America. The preliminary report of this committee, presented by the chairman, was read and fully debated at the meeting of the Council in February. It was a most careful, conscientious and able review of clinical teaching, showing how hospitals connected with medical colleges could be so managed as to insure to students practical, and, at the same time, most necessary advantages. Questions of general hospital management, endowment and equipment were considered, as upon them, in large measure, efficient clinical instruction must depend.

THE NATIONAL BOARD

To meet a situation which, under our peculiar form of government, has resulted in hardship, and must, if continued, cause countless embarrassments, a national Board of Medical Examiners has been organized, and will hold its first examination in Washington in October. The character and scope of this examination will be such that no state ought to, and we believe none will, deny recognition, in the fullest sense, to those who pass it.

At the same time, I wish to make it absolutely clear that such a board will not, cannot and should not interfere with the several state boards. Such an examination is for the exceptional, not the average man. It is for the man who, while young, willing and able to pass it, does so with the hope that it may prove a good investment for him in case of business opportunity, ill health in his family, or other impelling reasons which may cause him to change his location. All of us have in mind sad examples of able, even distinguished, general practitioners and specialists, who, compelled to remove from one state to another, were estopped from practicing their profession. Laws have been made, and rightly so, to restrain the ignorant and designing from imposing upon those whom the state would protect. That the state should insure the people protection in so vital a matter by placing its stamp upon medical practitioners cannot be questioned, and there is but one way in which this may be accomplished with equity and justice to all; that is, by requiring an examination at the hands of a state board of examiners. That conditions in all of the states are much better than those which existed prior to the formation of such boards cannot be questioned, for medical schools were given their first shock and made to improve by state boards, years before the Council on Medical Education was created; but the great number of states in our Union, some still maintaining multiple boards, makes a uniform standard simply impossible. Indeed, the boards of the several states not only differ in standard one from another, but the two or three boards in one state may differ as widely among themselves. Yet these differences are not only natural but also to a certain extent commendable, although especially trying and vexatious to practitioners who must move from state to state.

For many reasons a national board with power to confer a diploma carrying with it the unquestioned right to practice in any state — indeed, to follow the flag — has always been desirable, though, as yet, unattainable under existing laws. But there is a way by which such recognition may be accorded to a carefully selected and representative board, entitled of right to the confidence of the entire country, without changing the law in some states, and with but slight and immaterial changes in others. Many states have already, quite properly, given rather wide discretionary powers to their boards of examiners and invested them with authority either to recognize, or to withhold recognition from, extrastate agencies, domestic or foreign. This rests entirely with these boards, and they are governed solely by the standard of the body whose credentials are proffered. If high, they may be accepted without examination of the applicant; if low, they are rejected, and if doubtful, the candidate must be examined. No other course is reasonable. In some states the law is mandatory, and compels the applicant for licensure to be examined, in prescribed fashion, whatever his qualifications or credentials.

It should be a simple matter to induce all of the states at once to recognize a national board whose only aim is to improve the existing situation, and remedy a defect in our law and form of government, provided such board give an examination equal in every way to that required by the most exacting state in the Union. If this be done, then it becomes the patriotic duty of the several states to recognize its licentiates, just as the provinces of Canada now recognize the examination of its national Board of Examiners. There identically the same relations exist between states and general government as obtain with us, and there states' rights and jealousy of the general government prevented for more than fifty years the creation of a national Board of Medical Examiners. For several years past Canada has had such a national board, everybody is pleased with it, and all wonder how they got along without it. The president of the board explained its workings to us fully at the annual Conference on Medical Education in 1914. Shall we do less than Canada? Shall our states be less generous to their practitioners than her provinces? I do not for a moment think so.

The past fifteen years have witnessed a remarkable change in sentiment on the part of the several states toward the federal government. Many things formerly viewed, and resented, as encroachments upon the powers of the states are now not only accepted, but also eagerly sought by them or their representatives in Congress, and consequently all have been bettered. In no direction has a proposed change in our practice offered more to, and taken less from, the sovereignty of states than a properly constituted national Board of Medical Examiners will do. It proffers much; it takes nothing.

If questions of health, quarantine, pure food, the sale of narcotics, laws controlling the destruction of migratory birds, the granting of national charters, etc., have been yielded by states to the federal government — all of which has recently been done — why should there be the slightest hesitation on the part of any state to recognize the act of a national board of examiners, when by so doing it does not in the least surrender either authority or dignity? Certainly such a body, representative of the entire country geographically [illegible]l as through its public services and its leading national medical organizations, would be entitled to the same consideration—it asks no more—that is accorded a state board.

The government, without any authority in the premises, has, through the Secretaries of the Treasury, War and Navy, assented to the service upon such board of the Surgeon-General and an associate from each of these departments; and, in addition, has promised that the government laboratories, hospitals and schools for instruction may be used by the national board in conducting its examinations. The combined resources of these three government services are more than ample to meet every demand; moreover, they will insure an examination of such character as we believe to be necessary, yet is impracticable where large numbers of applicants are examined in one building, within a prescribed time, and by only a few examiners.

With the resources available to the board, a number of men can be examined in the several laboratories, some may be given a practical examination in the hospitals, while others undergo written, and still others take oral examinations, or operate on cadavers, all at the same time, but under different examiners.

An executive committee of five members is perfecting details for the first examination, which will be held from October 4 to 11, and longer if necessary, and, presumably, will be similar to that of the Conjoint Board of the Royal Colleges of Medicine and Surgery in England. An advantage, and a very great one it is, to those passing this examination, is the fact that they may subsequently become members of the Medical Reserve Corps of either the Army or Navy, if they so desire, provided that they fulfil the requirements as to age, and pass a satisfactory examination. The government gains also by the enlargement of these corps, and is insured sufficient medical officers in time of war, riot, pestilence or other exigency. Therefore, as I have intimated, it is the patriotic duty of all to support a board which can contribute so much to the national government in time of stress. Those who recall the Spanish War will vividly remember the difficulties which beset both our Army and Navy in obtaining sufficient medical officers. Many of those accepted were far from being up to the standard of the services; this I know, and, having been asked a number of times to recommend young men for the Army, remember how difficult it was to get them. I frequently discussed the matter with the Surgeon-General's office, as well as with Col. A. C. Girard, who was chief medical officer at Camp Meade, where I visited him and sent a number of contract surgeons from time to time.

The National Board has adopted the standard of the Council on Medical Education of the American Medical Association, and, in addition, will require at least one year of service in an acceptable hospital. These requirements will be rigidly enforced; that is, an applicant must give satisfactory evidence of having had the following:

(*a*) A diploma from a high school of good standing giving a four-year course.

(*b*) A satisfactory course in science, embracing physics, chemistry and biology, of not less than one year.

(*c*) Four years in a medical school of A grade.

(*d*) At least one year as intern in an acceptable hospital.

The hospital year is required for two reasons. First, no one should practice medicine independently, however well taught theoretically, until he has had prac- l training under experienced men, and this can be ·ed only in a hospital. Some colleges require it graduation, and some states demand it before ·e.

Second, I think it most desirable that those who pass the examination should have the option of becoming members of the Reserve Corps of the Army or Navy; but to insure this, all requirements must be met. A year's internship in a hospital is required by both the Army and Navy.

While the amount of the fee to be paid by each applicant taking the examination has not, as yet, been determined by the board, there is no doubt that it will be much in excess of that charged by state boards, yet less than the amount charged by the Conjoint Board of England (£42). In America distances are often great, which may, with some, add materially to the expense of taking the examination in Washington; and, over and above the fee paid the national board, every one must also pay the usual fee for registration in the state of his adoption. Recognition of one's qualifications to practice medicine and surgery, by a given state board, by no means absolves one from paying the customary fee, just as though one were examined. To be excused from examination is all that can be reasonably expected, and this must be considered a courtesy, not a right.

As to the personnel of the board, I can say that there will probably be fifteen members, several not having as yet been appointed. All sections of the country are to be represented. As at present constituted, the board consists of: Admiral William C. Braisted, Surgeon-General, U. S. Navy, chairman; Major-Gen. William C. Gorgas, Surgeon-General, U. S. Army; Gen. Rupert Blue, Surgeon-General, U. S. Public Health Service; Col. Louis A. LaGarde, U. S. Army, treasurer; Asst. Surg.-Gen. W. C. Rucker, U. S. Public Health Service; Commander E. R. Stitt, U. S. Navy; Dr. Herbert Harlan, representing the Confederation of State Boards of Examiners; Dr. Isidore Dyer, representing the Association of American Medical Colleges; Dr. E. Wyllys Andrews, representing the American College of Surgeons; Dr. Lewis B. Wilson, representing the Mayo Foundation; Dr. Victor C. Vaughan, representing the American Medical Association; Dr. William L. Rodman, secretary, representing the American Medical Association.

2106 Walnut Street.

Extermination of Sleeping Sickness on Prince's Island.—Portugal is rejoicing that the prompt and thorough measures taken by the national public health service have apparently stamped out sleeping sickness from its colony on the island do Principe, west of Africa, where it seemed to have established a permanent foothold. The glossinas have apparently been exterminated from the island, and the thirty uncured persons are isolated in a state hospital under the direct supervision of the public health authorities. The medical mission that has been in charge of the work has appealed to the central authorities to refuse admission to the island to persons and cattle from infected countries, and to require notification of every case of trypanosomiasis that may develop. Cattle raising should be restricted to the southern part of the island, and hog raising should not be allowed anywhere. The number of dogs should also be restricted. The commission did not limit its work to sleeping sickness, but instituted a general educational campaign in hygiene which the *Medicina Contemporanea* describes in detail.

THE NATURE AND TREATMENT OF BRONCHIAL ASTHMA *

ROBERT H. BABCOCK, M.D., LL.D.
CHICAGO

Until about five years ago, the nature of this distressing affection was a matter for considerable discussion. The very terms applied to it attest the uncertainty regarding its pathogenesis. Thus it was called bronchial, spasmodic, nervous and idiopathic asthma. The appellations "nervous" and "idiopathic" have reference to its obscure causation, while the terms "bronchial" and "spasmodic" denote rather an attempt to define its pathology, if, indeed, it possesses any definite pathology. By some writers the dyspnea was believed due to spasm, but even among these advocates, complete agreement did not exist. Hyde-Salter, Biermer and others argued in favor of spasm of the bronchioles, while Wintrich and Bamberger stoutly maintained inspiratory spasm of the diaphragm to be the condition responsible for the respiratory distress. On the other hand, Weber contended for a fluxionary hyperemia as the essential nature of the asthma. Then we find the Curschmann spirals or the Charcot-Leyden crystals advanced in proof of bronchiolitis as the cause, or rather as the pathologic condition present.

In the consideration of the etiology of this malady, it was believed that heredity played a conspicuous rôle, as shown by asthma in both parent and child. This was especially true in those cases which developed in early life. In all cases a marked nervous influence was believed to exist and to account for the development of the asthma in later years of life and in those asthmatics whose paroxysms were evoked by psychic or emotional impressions or by the wetting of the feet, as cited by Hyde-Salter. Then came the announcement by Hack and others that some cases of asthma were cured by operation on and removal of intranasal abnormalities, as spurs on the septum, etc. The relief afforded in such cases was accidental and led to no intelligent or scientific conception of the actual nature of the disease.

The treatment, accordingly, was purely empiric, and aimed especially at the relief of the paroxysm or at its avoidance. Atropin was vaunted by Trousseau, while potassium iodid was praised by others. For the relief of the paroxysms themselves, asthma powders, morphin, ether, etc., were employed without any intelligent conception of their mode of action aside from the belief that they overcame muscular spasm.

Such, in brief, was the unsatisfactory state of our knowledge and of our therapeutics of spasmodic asthma up to 1909. In that year, Auer and Lewis published an account of their experiments on guinea-pigs by the intravenous injection of fatal doses of horse serum or edestin, and of their discovery that death was due to asphyxia from inspiratory distention of the lungs. In short, it was found that anaphylactic shock in these animals manifested itself as a typical picture of bronchial or spasmodic asthma. Moreover, it was proved that the result was the same when the vagus nerve was cut, the spinal cord and medulla destroyed and powerful artificial respiration was instituted. That the lungs were acutely overdistended with air was shown by even small portions of them floating on water and crepitating distinctly on palpation. The experimenters concluded, therefore, that the extreme distention of the lungs was owing to tetanic contraction of the circular muscles of the fine bronchioles and alveolar ducts, and that this muscular spasm was of peripheral, not centric origin. Lastly, it is noteworthy that they found that a hypodermic injection of from 0.5 to 1 mg. of atropin was capable of preventing death from a dose of the foreign protein which proved fatal in the controls.

---

* Read before the St. Louis Medical Society, Feb. 13, 1915.

The foregoing observations on animals called attention to certain facts reported of the effects of serum injections, for example, diphtheria antitoxin, on persons who were sufferers from what is known as "horse asthma." In several instances, persons who had been sensitive to emanations from horses displayed, on receiving the preparation of horse serum, alarming symptoms which in a few cases resulted in death. Accordingly, it was suggested by Rosenau and Anderson, S. J. Meltzer and others that bronchial asthma in human beings might be a phenomenon of protein sensitization, or anaphylaxis, as it is commonly called. Impressed by this suggestion, I studied cases of asthma from a different point of view and soon became an ardent advocate of this conception of the nature of this distressing complaint.

Some of the cases which I shall refer to seem to set forth clearly the applicability of this theory to the etiology of asthma; but let me now present some of the facts regarding anaphylaxis as stated by Victor C. Vaughan in his contributions to the relationship between protein sensitization and disease or immunity.

When a protein foreign to the animal economy enters the circulation, certain body cells generate a proteolytic ferment which attacks and destroys the invading substance. This holds true whether the protein be bacterial or some stable body as egg albumin, the pollen of plants, horse serum or the emanations thrown off from animals, etc. According to Vaughan, this foreign protein, whatever be its source, contains two principles, of which one is toxic and in large enough doses may cause death, while the other sensitizes the animal and is characteristic of the protein. If the protein be introduced at short intervals and is not of an overpowering amount, the cells of the host split it up successfully, and immunity is established. But if the protein be introduced a second time after a period of two weeks or longer, and if it be in a considerable dose, the phenomena of sensitization or anaphylaxis occur.

Furthermore, the proteolytic ferment generated by the body cells is specific for that particular protein which called it into being and for no other. Moreover, the protective cells are capable of generating proteolytic ferments against as many different kinds of proteins as gain access to the blood. Consequently, an animal may become immune against or sensitized to a number of foreign proteins. Again, the body cells appear capable of storing up for an indefinite time, perchance for months or even years, their specific proteolytic ferment, so that a person sensitized to horse serum, for example, in the form of diphtheria antitoxin, may display the phenomena of anaphylaxis on a second administration of the antitoxin or other serum years subsequent to the initial injection. Lastly, the cells of the parent which have generated or stored up a specific proteolytic ferment seem capable of transmitting to the offspring the sensitization of the parent. In this way can be explained the liability to asthma, for instance, observed in several members or several generations of a family.

Finally, it should be borne in mind that the atrium or focus through which a foreign protein may gain access to the animal body may be varied. That is, the avenue of entrance may be parenteral, as an infective focus in the nose, throat, mouth, abdominal cavity, etc., or it may be through the digestive tract. In the last case, the sensitizing agent may be introduced in the form of some article of food, as cheese, shellfish, etc. Ordinarily the protein of the diet is absorbed as amino-acids which are again reconverted into that particular form of protein capable of utilization as nutriment by the body cells. But if, through some defect in digestion, a protein, as of lobster, does not undergo complete solution into amino-acids, and some one of the intermediate products is absorbed, it sensitizes the individual. Then if, after a sufficient lapse of time, twelve days or more, the same article of food is eaten and again passes into the circulation before its complete conversion into amino-acids, it occasions the phenomena of anaphylaxis, as, perchance, urticaria or an attack of bronchial asthma. It is only in this way that we can account for a paroxysm of asthma after an unusually hearty meal or the indulgence in some particular article of diet.

So many and varied are the causes that excite or precipitate an asthmatic seizure that at first thought it may seem absurd or impossible to explain their action on the basis of anaphylaxis. There are few complaints that display such apparently puzzling vagaries. Thus, one asthmatic declared he was sure to experience an attack if he slept on a pillow of goose feathers. The sensitiveness of some sufferers to emanations from horses or cats is well known. Hyde-Salter enumerates among the exciting causes a wetting of the feet, sudden emotion of grief, as in one instance in which an asthmatic learned of the unexpected death of his wife, an indigestible meal, constipation, the appearance of the menstrual function, etc. In some cases the sufferer may be unable to ascribe his attacks to any special exciting cause. Again, there are some asthmatics whose paroxysms of dyspnea come almost periodically after intervals of practical freedom from the attacks of their enemy. In others, the dyspnea is never wholly absent, being associated with the evidence of chronic bronchitis and becoming intensified at times into typical paroxysms of asthma. The state of the latter patients is truly pitiable, and it is these that tax our therapeutic resources to the utmost.

If, now, spasmodic asthma is to be explained on the hypothesis of protein sensitization, then we must assume the existence either of a focus in the body from which the foreign protein is absorbed, or that at some period, perhaps in childhood, protein sensitization occurred or that sensitiveness to a special protein was inherited from a parent, whether the protein be thrown off by animal, fowl or plant.

It might very naturally be asked why one individual shows his protein sensitization by a paroxysm of asthma while another does not, but instead may develop urticaria. At first sight this difference in reaction seems to contravene the claim made for the anaphylactic nature of asthma, or that this lack of uniformity warrants the inference of some specific asthma-producing protein. One cannot account for this difference except on some such hypothesis as a neurosis or perchance inherited sensitization, notwithstanding the fact that the experiments of Auer and Lewis show asthma in guinea-pigs to be independent of any influence on the part of the nervous system. Certainly anyone treating an asthmatic sufferer must gain the impression that neurosis plays an important part in the complaint.

On the other hand, experience with autogenous vaccines seems to indicate that the anaerobic bacillus discovered in the sputum of the case to be cited is in reality the *causa peccans*. At all events, in all of my cases to date this organism has been found, and has seemed to be the agent which in the vaccines did the most good.

Various foci may be the source whence protein is absorbed. Nasal polypi are not uncommon in asthmatics, and are thought responsible for the dyspnea through reflex bronchial spasm or hyperemia. But how explain the connection on the same hypothesis between asthma and chronic cholecystitis? A physician who had suffered from asthma for sixteen years at length developed symptoms due to gallstones. Believing that this condition still further increased the injury to his heart likely to result from his asthma, he decided on drainage of his gallbladder. This was done successfully, and to the surprise of both patient and surgeon, was followed by a remarkable effect on his asthma. So long as drainage of the gallbladder was maintained, the physician was free from his old enemy, and for the first time in sixteen years was able to remain at home and pursue his practice during the winter. When, however, drainage was allowed to cease, the asthma returned, but in a less severe form. The present state of this patient is not known to me.

How can this be explained on any other ground than that of absorption of a foreign (bacterial) protein? The same explanation holds with regard to nasal polypi. They are symptomatic of chronic ethmoiditis, and their presence in the nasal fossae interferes with free secretion, and hence favors absorption of bacterial protein from the ethmoid cells or from the nasal passages. Their removal does the same thing as did drainage of the gallbladder. This is attested by the fact that radical operation on the ethmoid by curettage has been followed in more than one instance by marked improvement, if not cure of the asthma.

Whenever, as reported by Hack thirty years ago, asthma is lessened or cured by the removal of intranasal abnormalities, it is because better drainage is secured and protein absorption is prevented. In like manner, when Hyde-Salter observed asthmatic attacks to coincide with menstruation, it is not unlikely that some condition such as pyosalpingitis existed, and menstrual congestion interfered with drainage and promoted absorption of bacterial proteins.

We now come to the consideration that in cases of long standing there is quite sure to develop a chronic bronchitis which of itself gives rise to cough and dyspnea even when positive spells of asthma are not present. It is this condition which sometimes accounts for the failure of complete cure following many operations on the nose or accessory parts. When chronic bronchial catarrh exists, careful examination of the sputum by cultural methods discloses various and often numberless bacteria. So long as expectoration is free, absorption is hindered; but whenever cough tightens, ample opportunity is afforded for absorption of bacterial protein and for the phenomena of protein sensitization in the form of asthma. This is well shown by the following case, which illustrates also the sort of treatment likely to prove efficacious in accordance with our newer conception of the disease:

Last July I saw a man who had suffered from asthma for two years, and for two months had been confined to his bed. He was unable to lie down, and physical examination disclosed the typical picture of bronchial asthma: short and ineffectual inspirations with prolonged expirations, chest distended and filled with whistling, wheezing râles that were audible at some distance, a dilated right ventricle and tense, accelerated, somewhat arrhythmic pulse. Cough was difficult, and expectoration scanty and tenacious. Close questioning could elicit no history of a primary focus save that he had catarrh and one loose tooth. He was told to apply epinephrin ointment to the inside of the nose, and was given a prescription containing among other things tincture of lobelia and fluidextract of *Grindelia robusta*. A nose and throat specialist was sent to examine the upper respiratory tract, but no condition that might explain the asthma was found. Next his loose tooth was extracted, and disclosed a small alveolar abscess which was thoroughly evacuated. Vaccines were prepared from the pus of this abscess, but owing to neglect or misunderstanding were never administered.

During this time the man was not under my personal observation, but had been removed to a hospital, and was not again seen by me until late in September. The man had improved after the cure of the alveolar abscess so as to be able to get out on pleasant days, but still suffered with asthma every night. At this time the heart was not much dilated, but the lungs were still filled with numerous dry and moist râles of chronic bronchitis. Accordingly, it was decided to have cultures made from his sputum and vaccines prepared. Rosenow did this work for me, and reported a few fusiform anaerobic bacilli in preponderating numbers, but also pneumococcus, *Streptococcus viridans* and *Streptococcus haemolyticus*. The anaerobic bacillus emitted a somewhat offensive odor, and was believed to be the real offender. Nevertheless a mixed vaccine was prepared, and of this, 0.1 c.c., or 2 minims, was injected. When the man reported after three days for a second injection, he asserted that he had lost his nocturnal asthma after the initial dose of vaccine. In all, about twelve injections were given in gradually increasing doses at intervals of from three to five days, with the result that he not only experienced entire relief from his asthma, but his bronchitis had vanished and he declared he felt perfectly well.

Convinced as I am of the anaphylactic nature of bronchial asthma, the foregoing case seems to me to point the way to the successful management of many if not most instances of this hitherto baffling malady. The first step, of course, is the discovery and removal if possible of the focus from which the protein is absorbed when, as in the case just narrated, this exists in the body of the patient. If, as in some individuals, the asthma is evoked by emanations from an animal or other extraneous source, we can do no more than try to protect against exposure.[1] It is probable that most asthmatics have some abnormality within the nose, accessory cavities, throat or mouth. This defect either furnishes the foreign protein or, if in the nose, obstructs nasal secretions and so favors the growth and absorption of bacteria. Consequently all these possible foci, and especially the ethmoid and teeth, should be painstakingly examined by a competent and wide-awake specialist. If these parts, nose, sinuses, tonsils, teeth and jaws are negative, as proved if necessary by the Roentgen ray, then search should be made in all other parts of the body, and no possible source of infection overlooked. A most minute inquiry into the history is often of the greatest value. Thus I recall a young woman whose asthma was found to have developed not long after what she called a cold, but which coryza had been attended by a profuse purulent discharge. This information led the way to a proper investigation, and a chronic ethmoiditis was discovered.

---

[1] The establishment of immunity to horse serum or pollen of plants is being attempted and may yet become a positive therapeutic measure.

In some cases, it may be a chronic bronchitis or a patch of pulmonary fibrosis with atelectasis that is furnishing the bacterial protein. In such a case, or when operative procedure has not wholly rid the system of infection, a vaccine should be prepared from the sputum or other discharge, and injected under proper precautions. Some cases will yield readily to such treatment, but others may be met in which repeated cultures and vaccines will be required, for in some cases of bronchitis the chief offending germ may not be at first obtained. Such an instance, now under observation, has proved most perplexing and disappointing.

Perhaps, some one might say, treatment by means of autogenous vaccines may be all right, but what are we to do for relief of the paroxysms while vaccines are being prepared or until our exhaustive study of the case has revealed the original cause of the trouble? This is a proper question, since our therapeutic ingenuity is often sorely taxed. There are a few old and tried remedies which are now known to be antagonists to anaphylaxis and the action of which is explicable on this theory. Thus Trousseau almost a hundred years ago recommended atropin as a preventive, and, singularly enough, Auer and Lewis discovered that from 0.5 to 1 mg. of this remedy injected into guinea-pigs would mitigate or prevent anaphylactic shock from doses of protein that proved fatal in the controls.

Besredka, according to Vaughan, states that alcohol and narcotics exert transient and slight prophylactic effect against the symptoms of protein sensitization. This probably explains the short-lived freedom from an attack which some asthmatics find from whisky, as well as the prompt amelioration usually afforded by a hypodermic of morphin or heroin, etc.

Ten minims of a 1:1,000 solution of epinephrin thrown under the skin are in most cases highly efficacious, and probably possess transient antispasmodic or antianaphylactic power. Pyridin, ethyl iodid and the highly vaunted asthma powders act in the same way very likely, while at the same time they excite bronchial secretions. Tincture of lobelia, aspidospermin, ipecac and *Grindelia robusta,* or other expectorant remedies may be of service by promoting expectoration and thereby lessening absorption of bacterial protein when there is extensive bronchitis. A patient of mine was completely free from his asthma for three weeks after having been etherized for a tonsillectomy, but got his asthma again so soon as he contracted a coryza.

To my mind, no line of management offers so much promise of cure of this obstinate malady as does the administration of autogenous vaccines, in addition to the discovery and removal if practicable of the source of the protein absorption; but the rub comes in the detection of the focus or foci of infection. Patience is required on the part of both patient and doctor, and we should not hesitate to call in the service of experts in some special line of surgery, as rhinologists, in our aim at a thorough investigation and treatment of the case. Therefore, the initial step in successful management is a correct diagnosis.

THE TREATMENT OF INFANTILE PARALYSIS

PRELIMINARY REPORT, BASED ON A STUDY OF THE VERMONT EPIDEMIC OF 1914*

R. W. LOVETT, M.D.
BOSTON

In the fall of 1914, I was asked by the State Board of Health of Vermont if I would undertake on their behalf the treatment of the cases of infantile paralysis occurring there in the summer of 1914, of which there had been 293. A private citizen had given to the State Board of Health a certain sum of money to be expended on an investigation into the epidemiology of the epidemic and on the treatment of the affected persons. Dr. Simon Flexner of the Rockefeller Institute consented to take charge of the epidemiology end of the inquiry, and I embarked on the enterprise of the treatment of these cases in December, 1914.

The problem of the treatment of so large a group of cases was of itself a new and difficult one. The physicians of these cases were notified by the State Board of Health of certain centers where clinics would be held, and I made five trips to Vermont, spending two days at a time there, for the purpose of prescribing treatment. Cases were grouped in Burlington, Barton, Montpelier, St. Albans and Rutland, the local hospital in each instance being utilized for the purpose, and to each of these places I went with my senior assistant, Miss W. G. Wright, and investigated and prescribed for the cases by groups. Every possible facility was afforded to me for this investigation, and the work everywhere was made easy and agreeable by the interest and cooperation of the physicians and by the very efficient assistance of the State Board of Health.

There applied for treatment at the clinics 235 cases, but a certain number of cases of other years were brought for advice, and a certain number of cases of other paralyses were brought, cutting down the number of the 1914 cases to 149, and it is from these 1914 cases that the conclusions presented are drawn.

All patients were stripped, and the muscles were individually tested as to function. Cases in babies, which could not be examined in this way, are not included in the report. The muscles were classed as wholly paralyzed, partly paralyzed, and normal. By wholly paralyzed is meant that no response could be elicited from a voluntary attempt to contract the muscle either in a contraction of muscular fibers or tightening of the tendon.

The condition of each muscle was then marked on charts, which I originally obtained from Dr. E. A. Sharpe of Buffalo, and these charts form the basis of the following analysis.

NATURE OF THE PARALYSIS

It became evident that partial paralysis was much more common than total. Of 1,452 muscles affected, 416 were totally paralyzed and 1,036 partly, that is, the relation of partial to total paralysis was as 2.5 to 1. The ratio of partial to total paralysis varied in individual muscles, a matter to be discussed later.

A curious phenomenon was several times observed, where part of a muscle was paralyzed and the other part not. This was observed in the deltoid muscle, where the anterior or posterior half might work independently of the other, and once in the pectoralis major, where the sternal and clavicular parts were separated by function.

---

* Owing to lack of space, this article appears in The Journal in abbreviated form. Reprints of the complete article may be obtained from the author on request.

The predominance of partial over total paralysis is of importance. The reason for it would seem to lie in the grouping and relation of the nerve cells in the anterior cornua of the cord. These cells lie in longitudinal bundles, which are naturally largest in the cervical and lumbar enlargements.

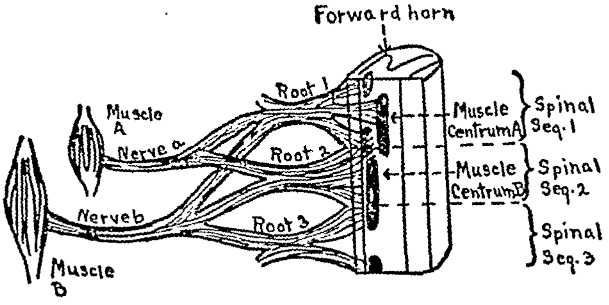

Fig. 1.—Radicular and peripheral muscular innervation. Muscle A supplied by segments 1 and 2; muscle B supplied by segments 1, 2 and 3 (Bing).

I quote from Bing:[4]

> Each contains fibers from several anterior roots, and, conversely, each anterior root distributes its fibers among several peripheral nerve trunks. . . . Anterior nerve root lesions, on the other hand, unless very extensive, merely weaken and do not completely paralyze the muscle, owing to the fact that as a rule the muscle is innervated from several roots.

Moreover, we must remember that the poison of infantile paralysis apparently reaches the cord by means of the circulation, and that the main blood supply is from the anterior spinal artery, horizontal branches from which enter the cord at each side at different levels, about 200 in number. The planes of destruction, therefore, are likely to be transverse, while the lines of nerve center association are longitudinal, so that in the case of a muscle which derives its innervation from a group of nerve cells occupying several segments, a transverse lesion may well leave certain centers intact, and some power may remain in the muscle.

This matter of partial paralysis is most important in the matter of treatment, as we shall see when we come to discuss the therapeutic measure of muscle training, because in such muscles there remains some initiative, and with it the power of developing more muscular volume and new associations by repeated passages of impulses from brain to muscle.

AFFECTION OF INDIVIDUAL MUSCLES

A tabulation was next made as to the affection of individual muscles, which shows that they were affected either partially or totally in the degrees indicated in Table 1. This table gives the number of total paralyses of each muscle, the number of partial and total paralyses, and the proportion of total to partial in each.

The main facts are that the quadriceps, gluteals and gastrocnemius lead in frequency, and that paralysis of leg muscles is much more frequent than of arm muscles. Abdominal paralysis existed in more than half of all the cases (seventy-nine), and affection of the muscles of the spine in more than a quarter (forty). The latter points have a distinct bearing on the occurrence of scoliosis, and indicate, I believe, that such affections are more common than had been supposed. The cases of abdominal paralysis were always symmetrical with two exceptions, one right and one left. This paralysis may occur as the only paralysis in the entire muscular system. When associated with paralysis of other parts, the association is always with leg muscles.

TABLE 1.—DEGREE OF AFFECTION OF INDIVIDUAL MUSCLES

Muscle	Number Paralyzed	Number Partial	Number Complete	Proportion of Partial to Total
Adductors	68	52	16	3.2: 1
Gluteals	133	106	27	3.9: 1
Flexors of hip	81	63	18	3.5: 1
Quadriceps	152	119	33	3.6: 1
Hamstrings, outer	97	66	31	2.7: 1
Hamstrings, inner	95	73	22	2.7: 1
Gastrocnemius	128	88	40	2.2: 1
Tibialis anticus	119	53	66	0.8: 1
Peroneals	96	40	56	0.7: 1
Deltoid	57	45	12	3.7: 1
Trapezius	49	42	7	6.0: 1
Infraspinatus	17	8	9	0.9: 1
Pectoralis	29	22	7	3.1: 1
Biceps	31	24	7	3.4: 1
Triceps	28	22	6	3.6: 1
Abdominal	79	64	15	4.3: 1
Latissimus dorsi	49	40	9	3.4: 1
Spinal	40	36	4	9.0: 1
Flexor carpi ulnaris	16	12	4	3.0: 1
Flexor carpi radialis	16	11	5	2.2: 1
Extensor carpi ulnaris	19	14	5	2.8: 1
Extensor carpi radialis	18	13	5	2.6: 1
Opponens pollicis	12	9	3	3.0: 1
Extensor pollicis	23	14	9	1.5: 1
	1,452	1,036	416	

The tibialis anticus and gastrocnemius are the only leg muscles which have been found to be affected by themselves without paralysis occurring elsewhere in the body. Of the former muscle, there were five cases of paralysis, of the latter three. Deltoid paralysis may occur alone in the arm.

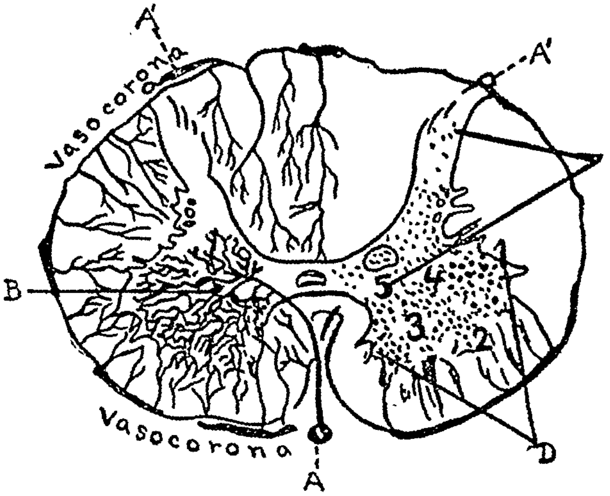

Fig. 2.—Distribution of blood vessels and nerve cells in the transverse section of the cord. *A*, anterior spinal; *A'*, posterior spinal; *B*, area of distribution of sulco-commissural artery; *C*, tract cells; *D*, root cells. 1, postero-lateral; 2, antero-lateral; 3, antero-mesial; 4, central; 5, postero-mesial (Bing).

The investigation of paralyses of the arm showed (1) that the paralysis was most frequent at the shoulder and diminished in frequency from the shoulder to the hand; (2) that the paralysis was severest (that is, that the percentage of total cases was largest) in the shoulder and diminished as one went toward the hand, and (3) that paralysis of the muscles of the left arm was very much more frequent than of the right arm.

---

[4] Bing, Robert: Compendium of Regional Diagnosis in Affections of the Brain and Spinal Cord, New York, Rebman Company, 1909.

These three factors will be considered and tabulated, and then the leg will be considered in the same respects, after which the possible meaning of these phenomena will be discussed.

Other facts about paralysis of arm muscles are as follows: In cases in which the muscles of the upper extremity are involved without paralysis occurring at other parts of the body, it is more severe in this region than when the muscles of the legs are also involved; that is, arm paralysis which is strictly regional is more severe than arm paralysis which exists in combination with more general paralysis. This statement rests on the analysis of fifty-eight cases.

TABLE 2.—FIGURES SHOWING THAT PARALYSIS OF THE ARM MUSCLES IS MOST FREQUENT IN THE SHOULDER AND DIMINISHES TOWARD THE HAND

Muscle	Total Paralysis
Deltoid	57
Trapezius	39
Pectoralis	29
Infraspinatus	17
Shoulder group	142 ÷ 4 = 35.5
Biceps	31
Triceps	27
Upper arm group	58 ÷ 2 = 29.0
Flexor carpi ulnaris	16
Flexor carpi radialis	17
Extensor carpi ulnaris	19
Extensor carpi radialis	18
Forearm group	70 ÷ 4 = 17.5
Opponens pollicis	23
Extensor pollicis	12
Hand group	35 ÷ 2 = 17.5

TABLE 3.—FIGURES SHOWING THAT PARALYSIS OF THE ARM MUSCLES IS SEVEREST AT THE SHOULDER AND DIMINISHES TOWARD THE HAND

Muscle	Total Paralysis
Deltoid	12
Infraspinatus	9
Pectoralis	7
Trapezius	7
Group	35 ÷ 4 = 8.75
Biceps	7
Triceps	6
Group	13 ÷ 2 = 6.50
Flexor carpi ulnaris	4
Flexor carpi radialis	5
Extensor carpi ulnaris	5
Extensor carpi radialis	5
Group	19 ÷ 4 = 4.75
Extensor pollicis	3
Opponens pollicis	9
Group	12 ÷ 2 = 6.00

With regard to paralysis of the muscles of the lower limb, the following facts were observed, which are of importance as contrasted with the similar observations in the arm:

1. The paralysis was on the whole more frequent at the hip, and diminished in frequency toward the foot; that is, the individual muscles in the upper segment were more often affected than in the lower (Table 5).

2. The paralysis was on the whole lightest in the hip, next lightest in the thigh and severest in the lower leg; that is, the proportion of total to partial paralysis increased as one went away from the hip toward the foot (Table 6).

RIGHT AND LEFT LEG

With regard to the relative frequency of paralysis in the right and left leg, the figures show in a total of 954 paralyses of leg muscles that there were 465 muscles paralyzed in left legs and 489 in the right, showing no especial difference in the affection of the two sides. This is a marked contrast to the predominance of left paralyses in the arm.

TABLE 4.—FIGURES SHOWING THAT PARALYSIS OF THE MUSCLES OF THE SHOULDERS, ARM AND FOREARM IS MORE FREQUENT ON THE LEFT SIDE THAN ON THE RIGHT

Muscle	Right		Left
Deltoid	24		33
Trapezius	18		21
Infraspinatus	6		11
Pectoralis	11		18
Biceps	11		20
Triceps	12		15
Flexor carpi ulnaris	7		9
Flexor carpi radialis	7		9
Extensor carpi ulnaris	7		12
Extensor carpi radialis	6		12
Extensor pollicis	5		7
Opponens pollicis	10		13
Total	124		180
Ratio	2	to	3 (very nearly)

TABLE 5.—FIGURES SHOWING GREATER FREQUENCY OF PARALYSIS IN UPPER SEGMENT THAN IN LOWER

Muscles	No.

Gluteals	133
Gastrocnemius	128
Tibialis anticus	119
Outer hamstrings	97
Inner hamstrings	95
Peroneals	96
Flexors of hip	81
Adductors	68

TABLE 6.—PROPORTION OF PARTIAL TO TOTAL PARALYSIS IN THE MUSCLES OF THE LOWER EXTREMITY

Muscles	Partial to Total
Gluteal	4.0: 1
Quadriceps	3.6: 1
Flexors of hip	3.5: 1
Adductors of hip	3.2: 1
Hamstrings	2.7: 1
Gastrocnemius	2.2: 1
Tibialis anticus	0.8: 1
Peroneals	0.7: 1

ANALYSIS OF PREDOMINANCE OF PARALYSIS IN LEFT ARM AND FREQUENCY OF DISTRIBUTION IN ARM AND LEG

Certain interesting problems are opened up by this study of arm and leg affections which demand analysis. The facts of paralysis occurrence are as follows: The muscles of the limbs nearest the trunk are more frequently affected than the distal ones; the left arm muscles are noticeably more frequently affected than the right. The leg muscles in the right and left leg are equally affected.

The facts of use or function are that the right arm is much more actively used than the left, not only more frequently, but also for more varied and complicated and finer movements; the legs are used equally It would therefore seem that muscles used actively, continuously and in a complicated way were more likely to escape than those less used, or used for simpler, less continuous work. One would suppose that the blood supply would be more free around the spinal centers where the motor activity was greatest and most complicated, and perhaps less free where the motions were less frequent and complicated. This would account for the predominance of left arm paralysis and the equal paralysis of both legs.

After these figures were worked out, it seemed that such a relation between right and left should appear more in older than in younger patients, because in the younger ones the differentiation between the right and left arms is of course less marked than in the older, younger children being much more nearly ambidextrous. If such a relation between right and left arms rested on a functional basis, it would be expected that there would be a larger proportion of left arm paralyses in older than in younger patients. In twenty-four patients 5 years old and younger, there were twelve left arms and twelve right paralyzed, a ratio of 1:1. In twenty-seven patients over 5 years of age (from 6 to 38 years) there were twenty cases of left arm paralysis and seven of right, a ratio of 3:1.

I should wish to acknowledge here my great indebtedness to Prof. W. B. Cannon and Assistant Professor Martin of the Physiological Department of Harvard University for much assistance on the physiologic side of the problem.

This also accords with the distribution of the paralysis in both arms and legs, which has been shown to be most frequent near the trunk. The demands on the hip and shoulder muscles are simple and less continuous than on the muscles of the lower leg and forearm or of the hand and foot. The latter are continuously active in small, fine, complicated movements, whereas the larger muscles nearest the trunk deal with the coarser and less frequent movements. The relation between the activity of the proximal and distal parts of a limb are not unlike those of the left and right arm in their relative use. It seems probable from these facts and this grouping that, on the whole, muscle centers given to finer, complicated, more frequent movements have a more active blood supply and are less likely to attack on their nerve centers from the virus of infantile paralysis than the centers of muscles functioning in heavier, less complicated and less frequent movements.

ANALYSIS OF SEVERITY DISTRIBUTION IN ARM AND LEG

In the next place, it has been shown that the muscles of the upper extremity are more severely affected nearest the trunk and less severely lower down, whereas in the leg this relation is reversed, and the largest proportion of severe paralyses is in the lower leg and foot. This is estimated on the proportion of total to partial paralysis in the individual muscles.

This puzzling phenomenon is more nearly correlated to the weight coming on each muscle in the activities of the upright position than to any other factor. The great majority of these patients were walking in some form or other, so that the weight-bearing position may fairly be taken into account.

At the shoulder, the deltoid, triceps and biceps all help to hold the arm up against the shoulder joint, and the weight to be met not only in this suspensory function, but also in attempted movements, is greatest at the shoulder and less as one goes down the arm, because the weight of the whole arm is obviously more than the weight of the lower one or two segments. Upper arm muscles, consequently, have more weight to handle than lower arm and hand muscles.

In the leg, on the other hand, the weight to be met in muscular function increases as we go from the hip to the feet, as of course there is greater superincumbent weight at the lower leg than at the hips, so that the lower leg muscles must raise more weight than hip muscles in walking, for instance. There is, of course, no proof that this variation in severity of paralysis is caused by this greater or less weight to be met in muscular function. The explanation accords with the facts, however, better than any other seems to do. Severity distribution cannot be connected with size of muscles, or function of a peculiar sort. It cannot be explained by local circulatory sluggishness affecting dependent parts. It is not associated with anterior or posterior muscles, nor is it easy to connect it with spinal localization. It seems purely a segmental limb distribution, and whether it is or is not the correct explanation, severity of paralysis is proportionate to the weight to be met by the muscles of the different levels, not because this factor influences in any way the original affection of the cells, but because it may retard the recovery of those muscles working against the greatest weight.

This suggestion has a direct bearing on the matter of treatment, for if it is correct it may be interpreted into showing the ill effects on muscular recovery of overuse, a matter which will be discussed later.

Infantile paralysis has been heretofore regarded as a haphazard affection of muscles, most frequent in the leg, and in the cord lesion it appears to have a purely accidental distribution most marked in the lumbar enlargement. It is possible, however, that there are other factors than the cord lesion which determine the ultimate condition of affected muscles. The analysis just made as to frequency and severity of paralysis shows that in cases some months after the attack there are apparently existing conditions not easily to be explained by the cord lesion alone, but suggesting that function, and especially the function of maintaining the upright position, may have something to do with determining the ultimate distribution.

ASSOCIATED PARALYSES IN THE LEG

Further pursuit of the inquiry suggested by the analyses just given takes up the question of muscular grouping in the leg. If the paralysis were a purely segmental affair wholly determined by the cord lesions, there would be in the limbs a roughly segmental distribution, muscles at the front and back of the thigh and front and back of the leg being more often paralyzed in this combination than in any combination suggesting associated function. In other words, opponents would be more often paralyzed in combination than would synergistic or functionally associated muscles at different levels.

The leg rather than the arm was selected for this analysis because of the greater simplicity of function in the former. In the arm, rotation movements complicate the more purely forward and backward movements of the lower extremity.

The inquiry then resolved itself into the investigation of whether associated or antagonistic muscles were most often paralyzed in combination in the legs.

The muscles in the leg most closely associated functionally are the gluteals, the quadriceps and the gastrocnemius, for they are the muscles which maintain the upright position. The gastrocnemius holds the tibia upright on the foot, the quadriceps holds the knee straight, and the gluteals hold the trunk erect on the legs. The associations were as follows: If the quadriceps is paralyzed, either the gluteals or the gastrocnemius or both are almost always associated with it. In 109 cases there were only two exceptions. In three cases the quadriceps had no association in the leg. In the 109 cases of quadriceps paralysis, to contrast with the 106 associations of gluteals or gastrocnemius, there were only fifty-eight associations of paralysis of one or both hamstrings. The quadriceps, therefore, is affected nearly twice as often with its associated muscles as with its antagonists.

When the gastrocnemius is involved, the quadriceps or gluteals were involved in 108 out of 109 cases; but the antagonists of the gastrocnemius, the extensor longus digitorum and the tibialis anticus, either one or both, were paralyzed in combination with it in only sixty-six cases.

EXPLANATIONS OF PREDOMINANCE OF ASSOCIATION PARALYSIS

This predominance of association paralysis is susceptible of several possible explanations, of which the following may be mentioned:

1. The muscles which maintain the erect position are all very large, and must have large centers composed of many motor cells. On account of their very extent, therefore, they are more likely to be affected than smaller muscles by a generally distributed destructive process in the cord. That this is not altogether acceptable is shown by reference to Table 1, in which it will be seen that the tibialis anticus and peroneals, which are small, are of high incidence, and the pectoralis major, a large muscle, is of low incidence.

2. The second explanation is that associated muscles may be so intimately grouped in the arrangement of their motor centers in the cord that they are more likely to be involved in the same lesion than opposed muscles would be. If, however, one may trust to the present data on the segmental innervation of these muscles, this view is not borne out.

3. The third explanation for the predominance of residual paralysis in associated rather than antagonistic groups may be in the functional relation of the muscles themselves. Three muscles, the gluteal, the quadriceps and the gastrocnemius, work together to maintain the upright position, and if a whole leg is lightly affected, it may be that the association of these muscles in function may retard their recovery by their intimate and necessary functional dependence on each other; especially if one were seriously affected, it might retard the recovery of the muscles associated with it by throwing more work on them than they were able to perform in their affected condition, which condition would not obtain with regard to antagonists.

At this stage of the inquiry, it is not possible fairly to choose either one of these three explanations as the one to be accepted to the exclusion of the others.

CLINICAL APPLICATION

Such are the facts elicited in this preliminary analysis.

I regard one point as fairly well established by these figures, namely that there is another factor beside the plain anatomic distribution of the lesion in the cord which determines something of the extent and severity of the residual paralysis.

The therapeutic measures at our disposal in fairly early cases are massage, electricity and muscle training.

Massage may be expected to improve the local and general circulation, to facilitate the flow of lymph, and to retard muscular deterioration. It cannot, however, be expected to facilitate the transmission of a motor impulse from the brain to the muscle.

Electricity is less highly regarded in the treatment than was formerly the case. The unintelligent use of electricity month after month to the exclusion of other measures has been one of the handicaps which has stood in the way of the best progress in many cases. It is quite possible that it may improve the muscular condition. Statements of its value rest as a rule on bare personal assertion or on the unusually rapid improvement of individual cases; but cases vary greatly in their rate of improvement, and the only way to judge of the value of electricity is to use it on one side of the body in bilateral cases and use the other side as a control. In the winter of 1913-1914, some cases in private practice were given daily treatments of galvanic electricity on one side and none on the other, while daily muscle training was being given by my assistant, who was not told which side was receiving the electrical treatment. At the end of some months she was asked if either side had shown more rapid improvement than the other, and no difference had been noted. This simply confirmed my general experience of many years of less careful observation.

Muscle training, on the other hand, rests on a sound physiologic basis, works out empirically better than any other of the measures, and the large proportion of partial paralysis in the cases observed shows its reasonableness.

OVERFATIGUE AND OVERUSE

We come now to the final, and what I believe to be the most important part of the paper, namely, the possible effect of overfatigue and the overuse of massage on returning muscular function, a phase of the treatment question almost wholly neglected.

If we take the case of a partly paralyzed muscle with some remaining power, we are anxious to bring about in that muscle the greatest possible return of functional power; that is plainly our object of treatment. Now the rational exercise of a normal muscle results in increase of size and power of that muscle, and presumably the result would be the same in a muscle weakened by infantile paralysis which was rationally and physiologically exercised or massaged. We are, however, dealing with muscles in many instances very weak and incapable of doing much work, and it must be an easy thing to overexercise them.

As to the question of this overuse, the following facts are suggestive: The majority of the early cases seen in Vermont showed partial rather than total paralysis; the gastrocnemius muscle in cases of early paralysis was quite different from the stretched, lengthened and powerless gastrocnemius muscle of late cases. Muscles partly paralyzed in which power is returning may be rendered functionless by slight grades of overuse. These considerations all have a bearing, and in connection with observations to be mentioned, indicate the possibility that in many cases of infantile paralysis we are encouraging in partly paralyzed muscles a function wholly beyond their ability, and are thus delaying their return of power and possibly converting partial into total paralysis. The observations follow:

It has been repeatedly observed in my private practice that power might begin to return in a very faint degree to a muscle while under muscle training, and that with care this power would steadily increase, but if that muscle were exercised even very gently every day, that power would diminish or disappear, so that we exercise such muscles only once in three days at the outset, increasing the work most carefully.

A young man under my care, severely paralyzed in both legs, six months after the attack showed some return of power in the peroneals. This developed and was exercised in the usual way, but he was so delighted with the new function that one year after the attack he tried it at intervals all of one day on the principle that if a little exercise were good a large amount would be better, and the power promptly disappeared, never to return in full amount after some five months.

A young man with a paralysis of the left arm acquired in Vermont in September, 1914, was brought from New York to see me in December, 1914. He was having massage and exercises daily from an apparently competent masseur, and was urged to use his arm as much as he could to stimulate returning function; but for a month he had not improved, and the parents therefore decided to send him to me for treatment. He could not, however, come to Boston for a month, and asked what treatment he should pursue in the meantime. A sling supporting the shoulder was put on, he was forbidden to use the arm except at meals, and massage was stopped. After a month of this routine he showed at least 25 per cent. of increase of power.

I saw with Dr. F. B. Percy of Brookline, Oct. 19, 1914, a child of 10 with a total paralysis of the anterior tibial muscle and partial paralysis of the gastrocnemius. Ten days after the attack, sensitiveness had gone, but the child could only walk badly and unsteadily. She was kept quiet for a month more, when she was allowed to walk a few steps daily. She made a remarkable gain, and massage and muscle training were begun, Jan. 6, 1915, although the amount of walking was not increased to any extent, the child walking only a very little. In four months the gastrocnemius and tibialis anticus had apparently nearly normal power when their resistance was tested by the hand, but the child still limped a little. Feb. 24, 1915, four months after the attack, the mother was asked to keep this child practically off of her feet for two weeks while the other conditions of treatment were the same. At the end of this time the limp had disappeared.

Oct. 5, 1914, I saw a child of 5 with nearly complete paralysis of one leg below the knee from an attack three months previous. The child walked badly, but was much helped by a brace to hold the foot at right angles to the leg. Muscle training was started, and the child improved satisfactorily, evidences of returning muscle power becoming plain. March 6, 1915, the mother made a statement that attracted my attention, namely, that the child walked better in the morning than at night. She was asked to keep the child off of his feet as much as possible for a month, restricting walking to the greatest possible degree. April 6, 1915, examination showed during the month a very striking increase in power in the muscles controlling the foot, and it was evident that the progress in the last month had been far greater than in any previous month, and the child walked as well at night as in the morning.

These illustrative cases seem to me to show that much smaller degrees of overuse may be deleterious than is generally supposed. Probably any of us would agree that gross and persistent overuse of partly paralyzed muscles would be undesirable; but it seems to me reasonable that in the early stage of returning power, we should be exceedingly careful in the use of muscles in walking and in the use of heavy and prolonged massage, much more careful than we are at present, if I may judge the practice of others by my own previous methods.

I hesitate to reason from an unproved conclusion in this connection; but may I once more call attention to the fact that the proportion of total to partial paralysis is greatest in the muscles which have the greatest weight to oppose in the standing and walking position and least in those which have the least weight, in a series of cases observed some months after the acute attack. If overuse is the harmful factor that I believe it to be in retarding recovery, its effect would be noted in just those muscles which show the highest proportion of total paralysis.

234 Marlborough Street.

EXPERIMENTAL STUDIES OF VARIOUS ANTISEPTIC SUBSTANCES FOR USE IN TREATMENT OF WOUNDS

BASED ON THE WORK OF SIR W. WATSON CHEYNE *

ROBERT A. KEILTY, M.D.
AND
JESSE E. PACKER, M.D.
PHILADELPHIA

The purpose of this paper is the experimental study of the antiseptic power and diffusibility of various substances commonly used to check bacterial growth. The study is based on and largely follows the report of Sir W. Watson Cheyne.[1]

The study by Cheyne grew out of a desire to prevent sepsis in the wounds of soldiers received while on duty in the trenches and at the battle front during the present war. As a result of these wounds, an enormous number of serious infections have occurred, followed by a high mortality. This is due in part to a delay in reaching the base hospital and in part to the large number of wounded needing treatment at one time. It was Cheyne's idea that each man should carry a convenient package of some antiseptic diffused in a proper vehicle which could be introduced into wounds immediately after their occurrence, thus preventing or retarding bacterial growth locally, until a thorough disinfection could be carried out at a more convenient time and place.

In a later communication as a result of this work, the British government is now forwarding two packages to each man in the navy, one a paste made up of 20 per cent. phenol (carbolic acid) in a lanolin base and the other a powder of equal parts of boric and salicylic acids. A paste was chosen as a vehicle because of its ease in handling, because of the danger of liquids being lost and because of the fact that the recesses of lacerated tissues are more easily reached. Cheyne advised a paste composed of lanolin, 6 parts, and white wax, 1 part. This proved best from every point of view according to his experience. In our own work we have used this, and find one made up of castor oil, 70 parts, white wax, 20 parts, and spermaceti, 10 parts, to be equally advantageous, to diffuse a little more readily and to be considerably cheaper.

---

* Read before the Pathological Society of Philadelphia, May 13, 1915.

[1] Cheyne, W. W.: Lancet, London, Feb. 27, 1915.

The relative inhibitory, germicidal power and diffusibility of various antiseptics used and the most effective strength was determined by incorporating them into the base and growing bacteria on a slab of agar-agar over the paste. It was found that blood clot and agar worked equally well, and our work has been confined to agar.

The general scheme is to place the paste on the bottom of a Petri dish underneath the slab of nutrient agar, and to inoculate the upper surface of the agar with a bouillon suspension of bacteria. The activity of the antiseptic can be easily judged by observing the presence or absence and extent of growth on the surface of the medium.

TECHNIC

In order to obtain comparative results, conditions must be exactly the same for each substance tested. Hence 0.5 gm. of the antiseptic substance is used in each instance. This is spread on a coverslip three-quarters inch in diameter. Where drugs are to be tested in liquid form, two thicknesses of filter paper three-quarters inch in diameter are saturated with the substance, and the experiment carried on as with the paste. The agar slab must be the same thickness in every case. For this Edmund's chamber is used (Fig. 1). This consists of two glass plates, a brass ring one-quarter inch in thickness, a small portion of which has been removed, and three heavy paper clips. One plate is sterilized by passing through a flame and laid on a support, and the brass ring is flamed and laid on the plate, the open portion of the ring at one margin. The second plate is sterilized and placed over the ring. These are bound together with the paper clips. This forms a chamber open at one point into which melted agar is poured and allowed to solidify. When solid, the paper clips are removed, and the upper plate and brass ring lifted. This leaves the agar slab on the lower plate. The coverslip with the paste is placed on the center of the exposed agar, care being taken to have the paste next to the agar. The lower part of a Petri dish is inverted over the agar, and the Petri dish, agar and glass plate turned upside down. With a platinum rod the agar is easily transferred to the Petri dish. A tube of melted agar is poured around the slab to hold it in place. Finally the upper surface of the slab is inoculated by gently stroking with two loopfuls of a bouillon suspension of bacteria. The suspension is made by transfering two loopfuls of a twenty-four to forty-eight hour bouillon culture to a tube of sterile bouillon. This technic is that used by Cheyne with but slight modification for convenience. The plates are incubated for twenty-four hours at 37 C. (98.6 F), and the results recorded. The results remain remarkably fixed after the initial growth, even for days and weeks.

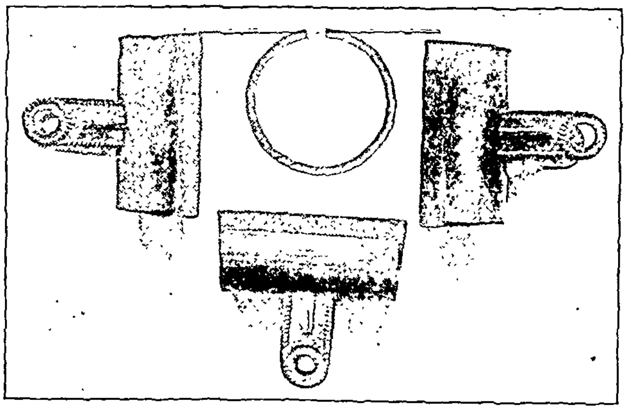

Fig. 1.—Edmund's chamber: a brass ring, two slides and three paper clips.

The organisms used in our work were the *Staphylococcus aureus, Streptococcus pyogenes* and *Bacillus coli.* It was found that substances inhibiting *B. coli* acted on the streptococcus to the same degree and on the staphylococcus to a greater degree, so that in most of this work *B. coli* has been used.

In comparative results the points observed include: 1. Is growth present and to what extent? 2. Is the growth directly over the paste? 3. How close to the margin of the paste does the growth extend? 4. What are the size and number of the colonies in relation to their distance from the paste?

From this comparison a convenient classification of the results may be given under three groups. 1. Those drugs which are markedly active. 2. Those drugs which are slightly active. 3. Those drugs which are inactive.

In order for a drug to fall under the first group, it must have not only antiseptic powers but also a wide range of diffusibility. The phenol group stands out preeminently, so much so that it is almost alone. Thus, too, the activity of the drug should be within a nontoxic dose as compared to common usage in an ointment, or as to its known absorbability in internal administration. Under the second heading drugs may be quite antiseptic locally, and yet according to this method show little or no diffusibility, except immediately over the paste, which means in distance a diffusing power of one-quarter inch through agar. Substances, for example, the dyes, may be quite diffusible and yet have little antiseptic power. If this range of diffusibility applies in vivo and the percentage of the drug used is carefully worked out, I see no reason why there is not offered a wide variety to be applied in the rational treatment of wounds not only in war but in civil life.

A summary of the substances tested follows:

1. Those drugs which are *markedly active;* under this we may include the following: tricresol, 10 to 20 per cent.; phenol, 10 to 20 per cent.; thymol, 10 to 20 per cent.; creosote, 25 per cent.; mercuric iodid, 10 to 30 per cent.; tincture of iodin, 5 to 10 per cent.

2. Those drugs which are *slightly active:* salicylic acid, 20 to 30 per cent.; Japanese powder, salicylic and boric acids, 20 to 30 per cent.; zinc chlorid, 20 per cent.; mercuric chlorid, 0.2 to 0.4 per cent. (in solution, 1:750, and 1:625); guaiacol ointment, 10 per cent.; mercuric ointment, 33 per cent.; creosote, 10 per cent.; carbolfuchsin (contains 5 per cent. phenol).

3. Those drugs which are inactive: iodin, 2 to 6 per cent. (crude drug); menthol and camphor, of each, 20 per cent.; boric acid, 30 per cent.; iodoform, 90 per cent.; zinc sulphate, 1 to 5 per cent.; alcohol absolute, alcohol methyl, alcohol, 95 per cent.; calcium chlorid, 20 per cent.; liquor formaldehydi, 0.1 and 0.5 per cent. (in solution 1:1,000, 1:500); lead nitrate, 5 to 10 per cent.; silver nitrate, 5 per cent. (in solution, 20 grains to 1 ounce); turpentine, 1 per cent.; ether, chloroform, Delafield's hematoxylin, sudan III, Loeffler's methylene blue, eosin watery solution; iodin green, glycerin, bismuth betanaphthol, 20 per cent.; salol, 20 per cent.; hexamethylenamin, 20 per cent.; zinc oxid, 25 per cent. scarlet red (2 per cent. scharlach R); bismuth subnitrate, 50 per cent; balsam Peru, ointment, 25 per cent.; scharlach R saturated solution.

It might be well here to include a little detail concerning some of the more important drugs. Of all the substances used, thymol and tricresol stood out prominently. This was noticed in two ways. They had a wide range of diffusibility, at the same time inhibiting the active growth of those few colonies which formed. Alone they were both active, while in combination this activity seemed somewhat increased. Tricresol was used in percentages of 5, 10, 15, 20 and 25. It was noticed that with *B. coli,* for instance, in a 5 per cent. paste, a diffuse growth took place over the entire surface but much thinner over the paste; in 10 per cent., no growth over and one-quarter inch beyond the paste; in 15 per cent., very few and small colonies on the outer one-quarter inch of the agar; in 20 per cent., no growth. Thymol had about the same action, and possibly from all standpoints showed a little more activity.

Many combinations were tried, including phenol, creosote, thymol, salicylic acid, mercuric iodid and tricresol in varying percentages. Out of this group tricresol and thymol were selected as the best. Tincture of iodin (Fig. 2) gave the following: in 0.5 and 1 per cent., growth over the entire slab; in 2 and 4 per cent., up to the filter paper; in 5 per cent., one-quarter inch beyond the paper, and in 10 per cent., no growth. Crude iodin in 6 per cent. in paste failed to inhibit the growth over the entire surface,[2] but this solution contains only a small amount of iodin: about 0.35 per cent. Salicylic and boric acids, in equal parts as a dusting powder known as Japanese powder, because of its use in the Russo-Japanese War, in a 30 per cent. paste seemed to be quite efficient.

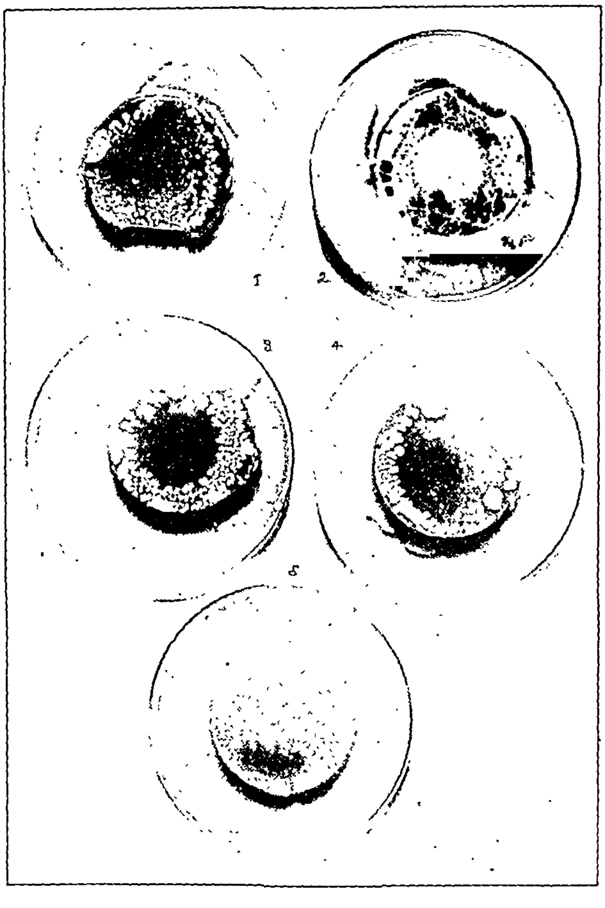

Fig. 2.—Tincture of iodin series: *1,* 1 per cent.; *2,* 2 per cent.; *3,* 4 per cent.; *4,* 5 per cent.; *5,* 10 per cent.

Those substances listed under the inactive heading in the percentages given all show diffuse growths over the agar slab. Silver nitrate, while it showed colonies over the entire surface, reduced the size of those colonies quite appreciably. Scarlet R (scharlach R 2 per cent.), a much used antiseptic, showed large colonies. Scharlach R in saturated alcoholic solution showed large colonies. Sudan III, an allied substance, showed quite an extensive growth.

From our experience, the following paste or ointment is recommended. Thymol and tricresol, of each, 10 per cent. in a base composed of castor oil, 70 parts, white wax, 20 parts and spermaceti 10 parts. Thymol and tricresol are more efficient in 15 and 20 per cent. pastes. They are recommended for use in 10 per cent. when infection has not taken place, or is superficial and not virulent, and in the higher percentages when the infection already exists or is severe. In the use of this paste, 1 dram of a 10 per cent. ointment represents 0.3 gm. or about 5 grains each of the antiseptic. Thymol internally in twenty-four hours has been recommended in dosage of 7 gm. in three hours (Wood). It is true that this is removed afterward by purgation. Pure cresol may be given internally in 2 to 3 minim doses (Wood). Cresol has the advantages of phenol with greater power, less irritation and lower toxicity. This statement may be open to criticism. However, we feel safe in recommending this ointment in dram doses of 10 or even 20 per cent. In the higher percentages, caution should be taken especially as to frequency of application. Since its object is a germicidal one, in these percentages one application should be sufficient with future asepsis maintained by less toxic substances. One of us has applied 1 dram of the 10 per cent. ointment, rubbing it well into the unbroken skin surface. There have certainly been no general effects and only the mildest local tingling. Examination of the urine before and two hours after the application showed no appreciable change in the sulphates.

CONCLUSIONS

1. The method as outlined by Cheyne offers an excellent means for the study, experimentally, of the diffusibility and antiseptic power of drugs.
2. The results obtained are confirmatory in some cases and startling in others as to the value of well-known remedies.
3. The phenol group and thymol give the best results as far as our work goes.
4. We are able to recommend an ointment composed of a base, castor oil, 70 parts, white wax, 20 parts, spermaceti, 10 parts, with tricresol and thymol, 10 per cent. each. Lanolin and wax may be used, but the vegetable base has some advantages.
5. These results are experimental, and must be borne out by clinical application. This we hope to do and report on in the near future.
6. The only drawback is the possibility of toxic effects, and this may be overcome by cautious usage in the amount applied and the interval between dressings.
7. This paste has a wide range in civil life as well as in war, and should prove more effective than those of common usage because of the increased percentages of the drug.
8. At the same time, the principle of the large dose is to establish at once or to maintain an asepsis in a wound, until ideal conditions for surgical treatment are available.

---

[2] In 10 per cent., mercuric iodid had a fair degree of diffusibility. Lugol's solution showed a growth over the entire surface.

THORIUM—A NEW AGENT FOR PYELOGRAPHY

PRELIMINARY REPORT

J. EDWARD BURNS, M.D.
Assistant Resident Urologist, James Buchanan Brady Urological Institute, Johns Hopkins Hospital
BALTIMORE

In order that a solution may be ideally suited for use in pyelography, it must fulfil the following conditions: It should be nontoxic, nonirritating, and quite fluid, so as immediately to escape from ureters and bladder, and present the greatest possible degree of opacity to the Roentgen ray, casting not only a good shadow but also one of clear delineation.

Various colloidal solutions of salts of the heavy metals such as iron, silver, bismuth, copper and lead, and suspensions of the salts of bismuth, calcium and magnesium have been tried. All of these solutions sediment on standing, and while being, for the most part, quite opaque to the Roentgen ray, are viscous, and some are quite toxic and irritating.

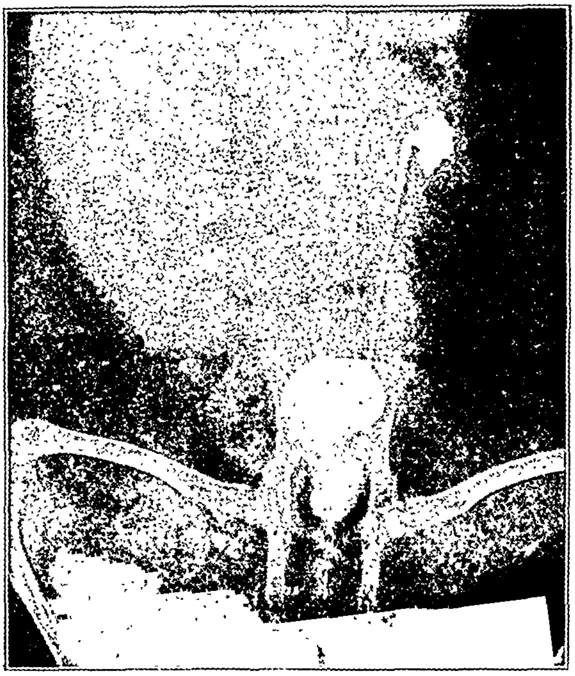

Fig. 1.—Rabbit's ureter and pelvis of kidney injected with 50 per cent. solution of thorium nitrate in distilled water.

Thorium nitrate dissolves readily in water, giving a clear, markedly acid solution, which, while being opaque to the Roentgen ray, is unsuitable for use because of its being an irritant, possessing a marked degree of astringency, and precipitating insoluble salts in the urine. This solution cannot be injected intravenously into animals because it causes intravascular clotting.

The neutral solution of thorium nitrate and sodium citrate, however, about to be considered, possesses, as far as observations made at the present show, all of the previously mentioned salient characteristics for use in pyelography. In this solution there seems to be a complex ion formation which changes both the chemical and pharmacologic action without causing any decrease of the opacity of the solution to the Roentgen ray. This solution also inhibits, but does not prevent the growth of ordinary bacteria. It flows readily, owing to its lack of viscosity, and escapes immediately from a ureteral catheter when injected into the pelvis of the kidney, or can be voided immediately if used in the bladder. It is perfectly clear to transmitted light, possessing a faint, yellowish tinge in large volume. It is perfectly clean and does not stain the clothing. From an economical standpoint, it

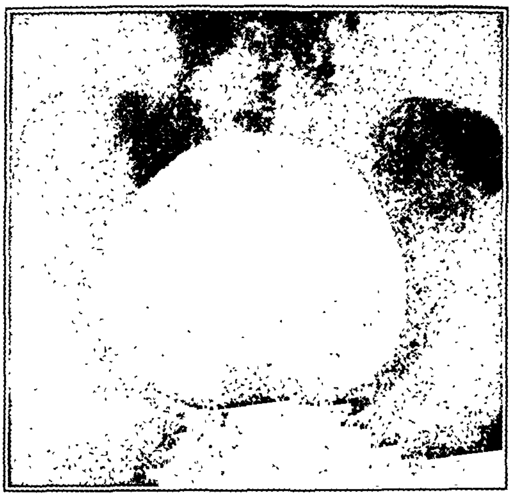

Fig. 2.—Normal bladder shadow. The bladder of this patient was injected with 350 c.c. of a 10 per cent. neutral solution of thorium nitrate and sodium citrate. Cystoscopic examination seventy-two hours after injection showed the bladder picture to be the same as before injection The patient experienced no discomfort after the injection, nor where there any signs of irritation.

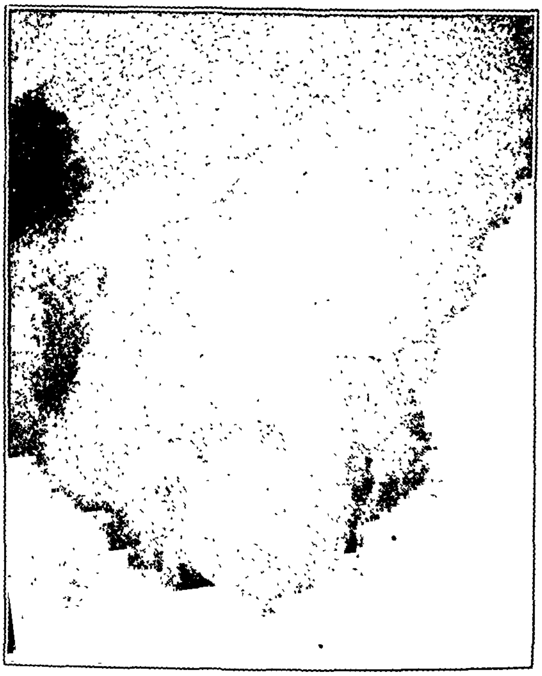

Fig. 3.—Trabeculated bladder with dilated internal sphincter, bilateral hydro-ureters and hydronephrosis due to congenital obstruction in the posterior urethra in a boy, aged 12 years. In this case, 600 c.c. of a 10 per cent. neutral solution of thorium nitrate and sodium citrate were allowed to flow in by gravity through a urethral catheter, the patient being in the Trendelenburg position while the picture was being taken. Cystoscopic examination, five days after the injection, showed the bladder picture to be the same as before injection. Phenolsulphonephthalein output and blood urea estimation were the same as before the injection. There were no signs of any irritative action.

has a decided advantage, being much cheaper than any of the silver preparations used at present, which are very expensive, particularly if used in quantities sufficient for bladder pictures and large hydronephroses. These preparations are also objectionable because they stain the clothing have such viscosity as to make injections through a small catheter difficult, are very irritating when they escape into the tissues, and have, as a matter of fact, been followed by death in several instances.

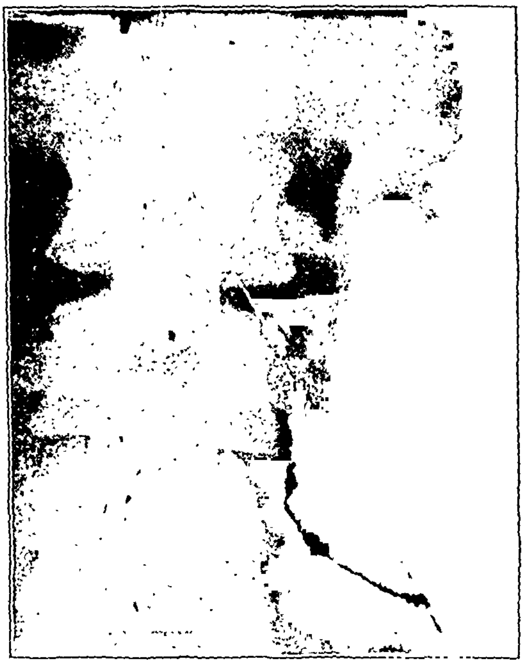

Fig. 4.—Renal pelvis and ureter. Seven and five-tenths c.c. of a 15 per cent. neutral solution of thorium nitrate and sodium citrate were allowed to flow into the pelvis of the kidney by gravity through a ureteral catheter. The phenolsulphonephthalein output was unaffected by injection; the solution caused no signs of any irritative action.

The solutions used contain 10 per cent. and 15 per cent. thorium nitrate and are made in the following way:

> To make 100 c.c. of a 10 per cent. solution, 10 gm. of thorium nitrate are dissolved in as little distilled water as possible; to this solution, kept hot on a water or steam bath, are added 30 c.c. of a 50 per cent. solution of sodium citrate, the additions being made in small quantities and care being taken to shake the solution thoroughly after each addition. At first after the addition of the citrate solution, a white gummy precipitate is formed which later becomes granular, and finally dissolves on the addition of all the citrate solution. This solution is then made neutral to litmus by the careful addition of a normal solution of sodium hydroxid, and made up to the required volume of 100 c.c. with distilled water. On filtration, a clear, limpid solution is obtained, which, when sterilized, either by boiling or steam under pressure, is ready for use. The stability of the solution is not affected in the least by sterilization.

The neutral solution of thorium nitrate and sodium citrate, prepared as directed above, is not irritating to the mucous membranes or peritoneal surfaces, does not precipitate salts in the urine, and can be injected intravenously up to 1.5 c.c. per kilogram of body weight and given by stomach up to 4 c.c. per kilogram of body weight in dogs without causing any change in the phenolsulphonephthalein output, blood urea content, hemoglobin content or cellular elements of the blood. No gastro-intestinal symptoms have been observed in any of these animals up to the present time. Complete protocols of these animals and further studies in regard to its pharmacologic action will be published in a subsequent paper. This solution may also be used in the roentgenographic study of the gastro-intestinal tract and other viscera.

The illustrations show not only the density of the shadow but also its clear delineation, when this solution is injected either into the bladder, ureter or pelvis of the kidney.

Further clinical studies are being pursued, and a report of their results will be published later; but the advantages of this neutral solution of thorium nitrate and sodium citrate for pyelography and other skiagraphic studies are so great that this preliminary report is now given. It is being used regularly in all our suitable urologic cases, and apparently is perfectly innocuous. If further experience confirms our present studies, it seems probable that we have in it a method of great value to urologists and roentgenologists.

SHORT CIRCUIT OF THE VAS DEFERENS

CHARLES MORGAN McKENNA, M.D.
Surgeon to St. Joseph's Hospital; Instructor in Genito-Surgery, College of Medicine, University of Illinois; Genito-Surgeon to People's and St. Bernard's Hospitals
CHICAGO

By short circuit of the vas I mean joining together the patent lumen of the vas with a section of the epididymis or testicle. Just a word regarding the anatomy of these parts in order to make the following clear.

The testis is composed of an enormous number of much convoluted seminiferous tubules, which fill up the intervals between the septums. These tubules form larger tubules, and finally make up the vasa efferentia, and on reaching the head of the epididymis form a larger tube which is called the canal of the epididymis. After a tortuous course, this ends at the globus minor and opens into the vas deferens. This is at the extreme lower pole of the testicle. The vas deferens begins at the tail of the epididymis and ends in the common ejaculatory duct, where it enters the prostatic or first part of the urethra.

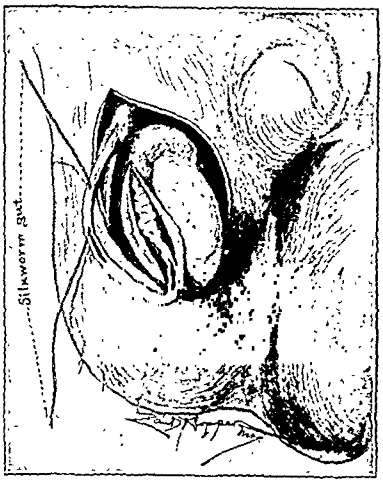

Fig. 1.—Exposure of vas deferens; silkworm gut in lumen of cord.

The operation under discussion is usually done to repair an old gonorrheal epididymis in which there is an obstruction of the vas between the tail of the epididymis and the external inguinal ring. It is of the greatest importance, therefore, to know whether that part of the vas is patent between the external inguinal ring and the opening of the ejaculatory duct into the prostatic urethra. This may be investigated at the time of the operation, but better should be done two or three days before the operation by drawing the vas through a small skin opening and injecting it with a solution of argyrol or collargol. By injecting the vas with either one of these solutions, the urine will become discolored a dark brown on first urination, hence, showing the vas between the incision and the prostatic urethra to be patent. If it should be found that the vas was not patent, it would be of no avail to do a short circuit operation, but Lespinasse's operation of the distal end of the vas becomes the one of choice.

Granting that the lumen is patent, the next point to be considered is the condition of the channel as to infection. It would be quite an error to go on with the operation if the seminal vesicle or ejaculatory duct contained any pathogenic organisms. I therefore wish to emphasize that it is quite important that the operator be absolutely sure that these parts are perfectly clean and will perform their duty if called on, provided one succeeds in opening the passage for the spermatozoa. If there is any doubt as to this condition existing in the seminal vesicle or ducts, these should be treated after Belfield's method.

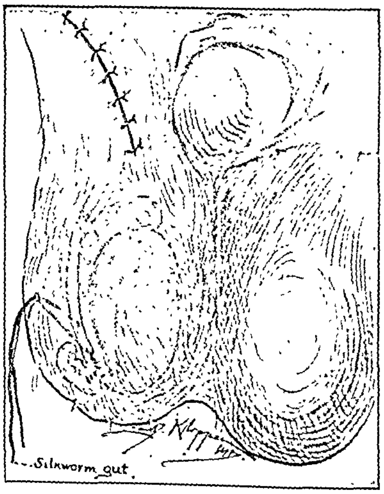

Fig. 2.—Anastomosis of vas with epididymis.

Dr. E. D. Martin of Philadelphia in 1900 tried this operation with success. He used four fine silver wires for the anastomosis and used the head of the epididymis as the base for the implantation. This was done on each side at different sittings, and at the second operation succeeded in getting free spermatozoa in the urethra.

Scatudo in 1901 tried the same operation by doing an implantation of the vas into the rete of the testis. In his case, he did a complete resection of the epididymis, using the argument that if it were tuberculous, he could still get free sperm direct from the testis. One of his dogs escaped without an examination being made, and the others did not show any live sperm.

Boarri in 1908 reported a case in which he succeeded in getting the sperm through direct from the rete in the testis.

My own work has been done mostly on dogs at the St. Joseph's Hospital. This is more or less of a preliminary report on the work thus far carried out. In the first three dogs operated on, the incision was made over the vas in close proximity to the epididymis. The vas was divided at this point and brought in apposition to a section of the epididymis, the incision in the epididymis being made in the head. In the first three cases, ordinary catgut was used to make the anastomosis, and as a result no sperm could be found in the urethra. In the next three cases, two were done the same as the first, and in the third a fine silver wire was used instead of the catgut, which was removed later. In the case in which the wire was used, no trouble was manifested in finding free spermatozoa in the urethra. Before doing the next two, I consulted Dr. Belfield, who explained that, while he had never tried it or seen anything in literature, he thought it would be a good scheme to introduce a silkworm-catgut in the lumen of the vas, and draw it out through the skin. This was done, and I shall show later in the technic of the operation how it materialized. In the last two dogs operated on, a side anastomosis was done instead of the end of the vas being used as at first. The silkworm-catgut introduced in the lumen of the vas was not used as an anastomosing suture, but as a means to leave the lumen patent and remove any blood clot that might tend to obstruct the vas after the operation. This plan worked perfectly in all cases, even in one case in which the vas was crossed over to the opposite epididymis.

The work on man so far consists of six cases, five of which can be reported. Out of these five, two have passed living sperm, three have not passed any, and in the last one, sufficient time has not elapsed between the operation and the time of the writing of this paper. I feel that I am somewhat to blame for the nonappearance of the sperm in these cases. While there had been success with the operations performed on the lower animals, it is quite a different thing to operate on man when pathologic conditions exist. The error was made in doing the anastomosis, the head of the epididymis, instead of the tail, being always used. The selection of the portion of the organ to be used depends altogether with the operator. This may or may not be in the extreme tail of the body.[1]

It is not a good plan to do the anastomosis unless plenty of free motile spermatozoa can be found. Free spermatozoa cannot be mistaken by the naked eye when there are enough present. The appearance of sperm in the vas is that of white milky pus passing through blood. After a few observations there will be no difficulty in locating the best field for the implantation. But considerable time should be spent in locating a suitable section for the implantation, to assure the patient a fair prognosis. Thus far. I have had no difficulty in finding the motile sperm in the tail of the epididymis or one-fourth inch above the tail. In one of the cases in man in which operation was performed, the amount of sperm was so much that I was sure there must have been some pus still remaining in that section of the epididymis. Before the operation was completed, a slide was covered with the fluid and sent to the laboratory for diagnosis. Dr. George Dick made a microscopic report which showed the slide to be completely covered with living sperm. In this case sperm was found afterward in the urethra.

TECHNIC

I base my technic for short circuit or transplantation of the vas deferens on the contention that vas operations should follow out sound surgical principles as used in surgery in other parts of anatomy. Some of the important points are:

1. Clean exposure and fixation of the cord.

---

[1] In one of the first cases reported in which the head of the epididymis was used for the implantation, the second and fifth nights after the operation the patient had an emission in which blood and argyrol were found in the discharge. This was certainly a proof that the operation was a success, and if free spermatozoa had been present they would have passed through.

2. The patency of the vas between the incision and the ejaculatory ducts. (This information is obtained by doing an injection of the vas previous to the present operation, Belfield's method.)

This operation is indicated when the occlusion is below the internal inguinal ring. The procedure is as follows:

The patient is cleaned and prepared as for any other surgical interference, except that tincture of iodin is not allowed to touch the scrotum in order to prevent excoriation. The patient is put under general anesthesia and placed in a slight Trendelenburg position. An incision is made in the same location as in operating for inguinal hernia and carried to the pendulous portion of the scrotum. The vas and epididymis are exposed at this point. A tenaculum or volsellum forceps are placed about the cord at its junction with the epididymis. A silkworm-gut is carried underneath the vas about 3 or 4 inches above the forceps. This is done to fix the cord in order that a clean field may be maintained, and makes the entrance to the vas easier for the operator.

The vas deferens is stripped of its covering for 2 or 3 inches above the epididymis by gauze dissection and Kocher director. Great emphasis is laid on this point as it expedites the operation and prevents any error in getting in its longitudinal axis in the lumen of the vas. An incision is made into the vas about one-half inch long. A fine pointed bistoury is the best instrument for this purpose. The incision is made about 2½ inches above the head of the epididymis. A piece of silkworm-gut is introduced into the lumen of the tube by means of a long hypodermic needle. The thread is put into the proximal end of the needle and pushed in just to the distal margin. The needle is now placed in the incision already made in the vas and pushed into the lumen of the cord above to the incision, and the point of the needle is brought out through the wall about 2 inches above the lower opening. The thread is drawn through the needle at this point, and the needle withdrawn through the lumen of the vas, thus leaving the silkworm-gut extending from the incision below and out through the wall 2 inches above, both ends of the thread being free. I wish to mention here that this is Dr. William Belfield's suggestion, and to him I wish to give all credit. Two sutures of chromicized catgut are placed through the incision already made in the vas and brought down into the opening made in the epididymis. The sutures are tied for permanent fixation, thus making the anastomosis of the vas with the epididymis and out through the skin, the sutures being tied loosely on the outside. These stitches are left in for from ten to fourteen days in order that the lumen of the vas may remain open. The tunica is closed in the regular way, as are the rest of the anatomic structures. The wound is healed and the scrotum put in a well-elevated position. The patient remains in bed from seven to ten days, at which time the skin sutures are removed.

The scrotum is carried in a suspensory from four to five weeks after the operation in order that no pressure be brought to bear on the anastomosed vas. Intercourse should not be allowed until six weeks after the operation.

CONCLUSION

I wish to emphasize the following points:

The vas should be free from infection.

The section of the epididymis used should contain plenty of free sperm, and the tail used for implantation.

108 North State Street.

Vital Statistics and Sanitation.—A nation that does not consider it necessary, or that is not able to provide adequate means for registering the births of its own children, or for officially recording the deaths of its citizens, can hardly be supposed to attach sufficient value to human life to enable sanitary measures for its conservation to be adequately carried out.—C. L. Wilbur, quoted by Irving Fisher, Memorial Relating to the Conservation of Human Life.

New Instruments and Suggestions

A PRACTICAL METHOD OF APPLYING THE WAX-TIPPED CATHETER IN THE DIAGNOSIS OF URETERAL STONE IN THE MALE

Frank Hinman, M.D., San Francisco

It is barely three years since the valuable wax-tipped catheter method of diagnosis of stone in the ureter, introduced more than twenty years ago by Howard A. Kelly of Baltimore, for use in the female, was adapted by Burton Harris for use in the male. The adaptation proposed (1912) by Harris has several objections: 1. The difficulty, trauma and pain of passing the cystoscope are increased. In the procedure the wax-tipped bougie is first passed into a full bladder, and the cystoscope, with its catheterizing telescope in place, is then threaded down the urethra over this bougie as over a filiform. Naturally the beak of the instrument must scrape along the catheter, and the window of the instrument, having no obturator, adds to the roughness and difficulty. 2. Security against scratching the waxed tip, whose position in the bladder is unknown on the insertion of the cystoscope, is not absolute. 3. The cystoscope must always be withdrawn from the bladder before the catheter is removed from the ureter.

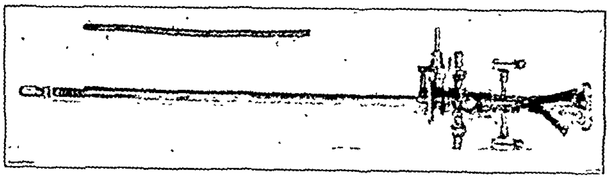

Fig. 1.—Preparation of wax-tipped catheter sheath: A soft rubber urethral catheter which will pass freely through the operating cystoscope (No. 9 or 10 F. for Brown-Buerger instrument) is passed into the cystoscope until the end projects a little beyond the elevator of the instrument. The other end is cut and slit up so that when the two slit portions are turned back over the mouth of the telescope they will hold the catheter in this position.

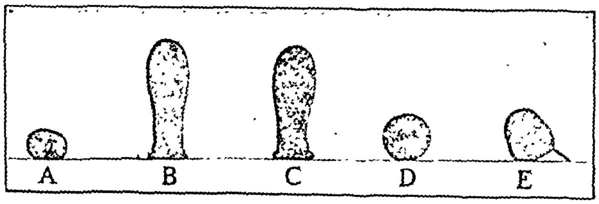

Fig. 2.—Method of making rubber tips for the operating telescope from small pipet bulbs: *A*, large rubber tip with single perforation on the market. This is too small for use with the rubber sheath; *B*, plain rubber pipet bulb, 3 cm. in length; *C*, bulb divided into three equal parts; *D*, first part placed inside of third and fastened with two silk sutures; *E*, single perforation in bulb, made with hot needle.

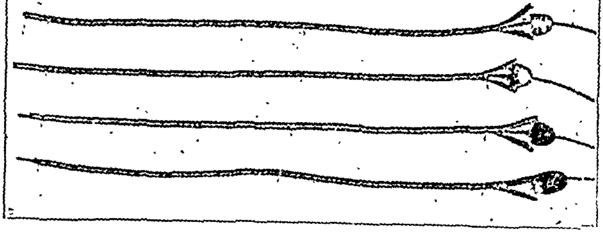

Fig. 3.—Rubber sheaths with wax-tipped catheters: In the upper two the tips are about 1 inch from the end, the position in which they should be, both for insertion of sheath into cystoscope and for withdrawal of sheath and catheter for examination of the waxed end. The rubber tip at the slit end of the sheath serves to mark and hold the catheter in this position. In the lower two the catheters have been pushed through for examination.

A simple procedure, which overcomes these disadvantages, has been used recently in several cases with entire satisfaction. It eliminates completely the added difficulty and pain in passing the cystoscope. It gives perfect security against extraneous scratches, and it permits the removal of the wax-tipped catheter for examination without previously withdrawing the cystoscope. The latter is a great advantage. Several control waxed tips may be passed one after the other, thus confirming the findings or accurately measuring the distance of the stone from the ureteral orifice. At the same time, and through the same cystoscope, an ordinary ureteral catheterization followed by functional study, ureteropyelogram or even both may be made, thus obtaining complete information in the case at the one cystoscopy.

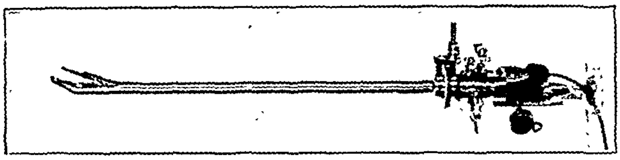

Fig. 4.—Catheter sheath fastened in place by rubber tip. The elevator of the instrument has been raised, showing how the rubber sheath protects the waxed tip.

The operating cystoscope (Brown-Buerger is used, but the method is applicable with any operating instrument) is passed into the bladder as for ordinary cystoscopy, the obturator withdrawn, the bladder washed out (the irrigating fluid should not be too warm, as it may soften or melt the wax), and the operating sheath of the instrument then inserted. The wax-tipped catheter has been provided with a soft rubber sheath, which should easily pass through the operating barrel of the instrument, as shown in Figures 1 and 3. The usual rubber tip (Fig. 2 *A*) for the irrigating instrument is too small to cover the orifice of the telescope when the slit ends of the rubber sheath are turned back. A very satisfactory tip may be quickly made, as indicated in Figure 2 *B*, *C*, *D* and *E*. In fact, this tip will be found to be much more satisfactory for all work with the operating cystoscope than the hard, friable tips on the market. The method of passing the wax-tipped catheter is indicated in Figure 4. The sheath with its catheter inside (to within 1 inch of the end) is threaded into the instrument until the end of the sheath appears in the visual field just beyond the end of the elevator of the instrument. The slit portions of the other end of the sheath are then spread to the opposite sides and covered by the rubber tip, which thus securely holds the sheath in place and insures dryness. The waxed tip is now carefully pushed into the field (Fig. 5), the elevator, which strikes the rubber sheath and not the catheter is raised, and the catheter then pushed on up safely by the beak of the instrument into the ureter (Fig. 4).

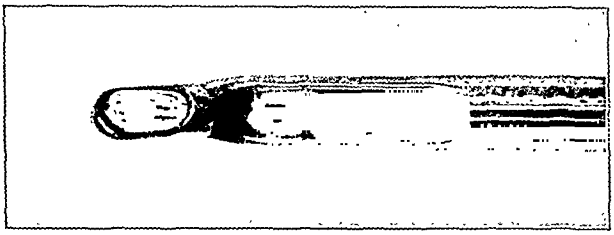

Fig. 5.—Waxed tip and rubber sheath before raising the elevator of the cystoscope.

In removing the wax-tipped catheter, after passing it up the ureter as far as desired, the lever of the instrument should be kept partially elevated; the waxed end can then be withdrawn into its sheath with no danger of striking the beak of the instrument. It is preferable to withdraw the sheath with the catheter in it, rather than to withdraw the catheter through the entire length of the sheath, for examination. In this way the waxed tip will have passed only a very short distance through its sheath, being originally retrograded into it to a distance of about 1 inch, and, before examination and after having passed up the ureter, not being withdrawn into it to a greater distance than this.

Physicians Building.

A NEW LID EVERTER

Sidney Israel, M.D., Houston, Texas

This small lid everter is the outcome of an endeavor to find an instrument that would give a large exposure of the entire upper lid and culdesac. Its most salient features are simplicity of design, ease of manipulation, and freedom from causing pain in introduction. It has been the means of revealing several cases of trachoma that had been overlooked by ordinary methods.

In introducing the instrument, it is grasped at its distal end between the tips of the thumb and index finger. With the patient looking down, the lashes of the upper lid are held in the tips of the thumb and index finger of the left hand. The knobbed ends of the instrument are then placed gently on the upper lid about one-half inch from the ciliary margin with the instrument in the vertical position. With the fingers of the left hand holding the lashes, the lid is retracted over the knobbed ends, and with gentle pressure on the distal end, the entire under surface of the upper lid, including the culdesac, is freely brought into view. In this position the knobbed ends can be slid from the outer to the inner canthus, exposing any part desired. In this position also, with the under surface of the lid exposed, the hold on the eyelashes by the fingers of the left hand can be released, and with the tip of the index finger of the right hand on the distal end still maintaining the position of the instrument in the vertical meridian, the thumb of the right hand can be dropped down to hold the lashes in place to maintain a complete eversion of the lid, while with the left hand free, any foreign body that is present on the under surface of the lid is easily removed.

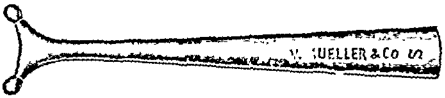

Fig. 1.—New lid everter.

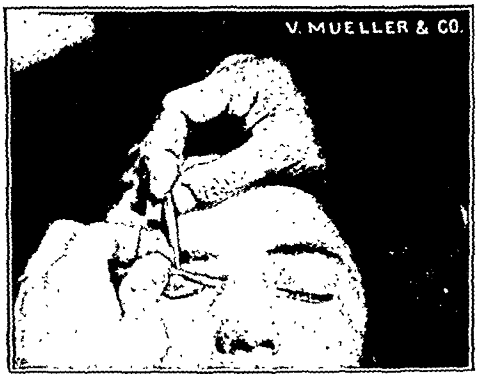

V. MUELLER & CO.

Fig. 2.—Method of using the lid everter.

The instrument can be readily carried in the pocket, and because of facility of introduction, can be used universally by the general practitioner and the ophthalmologist.

IMPROVED FORM OF BRAIN EXPLORER

Harold Gifford, M.D., Omaha

In the *Laryngoscope*, January, 1914, I described a brain explorer consisting essentially of two knife blades held together with a spring, to be used in cases of suspected brain abscess in place of the exploring needle or scalpel. As is well known, each of the latter instruments may pass through the wall of an abscess, and either on account of thickness of the wall or thickness of the pus, may not reveal its presence. The practice of passing in dressing forceps and opening them here and there in the brain can hardly be called either accurate or elegant. With this brain explorer, one passes the instrument into the brain as far as one thinks necessary, and then opens the blades; if no pus escapes, they are closed and passed on, being opened from time to time until they have gone as far as is permissible in any given direction. One can be sure after having done this that no pus in this particular tract will be left undiscovered.

Since my first article was published, I have modified the instrument, because on using it I found there would be a decided advantage in having the spring set off at an angle from the main axis of the blades. This greatly facilitates the introduction of a drainage tube or other drainage apparatus into the cavity of the abscess when the latter has been found. When the abscess has been penetrated and pus found, the instrument is kept in position until the drainage tube or gauze has been introduced into the cavity between the separated blades of the explorer, which have been grooved on the inner side to facilitate the introduction of a glass tube. The opening in the abscess wall can be enlarged to the desired extent by the closed blades of the explorer, or, if preferred, this can be done with a blunt-pointed bistoury introduced between the blades.

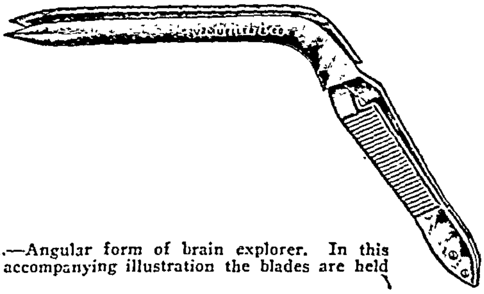

Fig. 1.—Angular form of brain explorer. In this ana the accompanying illustration the blades are held apart.

Since I first described the explorer, I have had occasion to use it in three cases of brain abscess. In two of these it worked most admirably. In one of them, the abscess was deeply situated in the frontal lobe, and it is a very open question whether the ordinary instruments would have opened it successfully. This patient on account of disagreement with the internist in charge, passed out of my hands to that of another surgeon, and what the final outcome will be, remains to be seen. Another patient with a large temporosphenoidal abscess is now, after three months, apparently perfectly well. In the third case, the abscess was a very small one originating apparently from the sphenoid cavity, and was situated so far back, and so close to the median line, that although a careful search was made for it, it was missed, and the patient died.

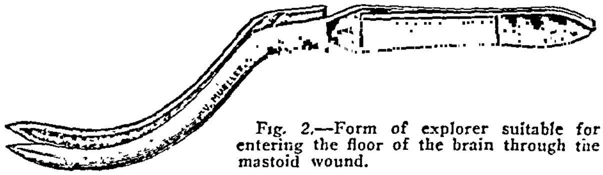

Fig. 2.—Form of explorer suitable for entering the floor of the brain through the mastoid wound.

In speaking of this instrument, which I have had in mind for a number of years, I have always said that the principle of it was so obvious that the idea must certainly have occurred to many operators beside myself, and I have found since my paper was published that West and Scott of London, in their excellent book on aural surgery (Blakiston's Sons & Co., 1909, p. 106), figure an instrument which they call an expanding trocar, which is made to be used in the same way. This, however, has such narrow, short blades that it must be decidedly less effective than the explorer here shown.

Beside the angular form of explorer (Fig. 1), I have had one made with curved blades (Fig. 2) for use on the floor of the brain. This form enables one to enter the temporosphenoidal lobe through the mastoid wound much more readily than could be done with the straight blades.

A COMBINED STAINING METHOD FOR MALARIAL PARASITES AND BLOOD SMEARS

Frederick F. Russell, M.D., Ancon, Canal Zone, Panama
Major, Medical Corps, U. S. Army

In this country the most popular blood stain is Wright's modification of the Romanowski method; in England and the English colonies, Leishman's stain is used almost exclusively, while in Germany, Giemsa's is the favorite. These stains and their many modifications are all excellent for chromatin, but as ordinarily used they fail to bring out the cytoplasm of the malarial parasite with the sharpness and distinctness obtained with Manson's borax methylene blue. The latter, until the Romanowski was simplified by Leishman, Wright and others, was the best we possessed for malarial parasites; in fact, for routine work it is still used by many.

The advantages of Manson's stain may be briefly stated as follows: 1. Cheapness, permanence and simplicity of preparation. It is made by dissolving 5 gm. of borax in 100 c.c. of boiling water and adding 2 gm. of methylene blue, medicinally pure; when cool the volume is made up to 100 c.c. and the stain is ready for use. 2. The clearness and distinctness with which it brings out the cytoplasm of the malarial parasite. 3. The rapidity and simplicity of the staining technic. The smear is fixed for a few moments in equal parts of alcohol and ether, or methyl alcohol, and allowed to dry; it is then immersed in a very dilute solution of Manson's stain for from ten to thirty seconds, washed in water and dried. 4. It also shows well the basophilic degeneration of the erythrocytes.

Its disadvantages are that: 1. It fails completely to show the nuclear chromatin of protozoal parasites. 2. It fails to bring out the granulations in the leukocytes. Because of these two defects, Manson's stain has fallen into disuse in this country in spite of the fact that it stains the cytoplasm of the malarial parasite better than any other.

The disadvantages of the methyl alcohol stains of Leishman, Wright, Hastings and MacNeil are: 1. Their expense; it requires approximately 1.3 c.c. for each slide, and methyl alcohol of proper quality is costly. 2. The rapid evaporation of the stain on the slide, with resulting precipitation; this is especially troublesome during the windy season in the tropics. In Vera Cruz, for example, it was difficult to obtain clear preparations unless the slide was protected during the staining by a bell jar. 3. Great care and watchfulness are necessary to success in staining. 4. With none of these stains is the cytoplasm of the malarial parasite so clear and distinct as with Manson's stain. The stain of Giemsa belongs to this class, although it is used in aqueous solution; it is slow, expensive, practically impossible to obtain except from Gruebler in Leipzig and while it gives excellent chromatin stains, the cytoplasm is not well brought out.

The advantages of the methyl alcohol stains are: 1. The rapid and perfect fixation. 2. The clear and beautiful staining of the chromatin of the nucleus. 3. The production of Schuffner's dots in the erythrocytes in tertian malaria. 4. The beauty and distinctness of the nucleus, cytoplasm and all classes of granules in the leukocytes. 5. The distinct staining of the blood platelets.

It is evident that an ideal picture would result if the best of the methyl alcohol chromatin stains could be combined with Manson's cytoplasmic stain. After several attempts the following method was found to give the best results and it has been used for the routine of the laboratory for thousands of blood preparations:

1. Fix and stain for two minutes in Wright's or similar methyl alcohol stain. It is most convenient and economical to use about 50 c.c. of stain in a Coplin jar; the top should fit well to prevent evaporation and the stain may be used repeatedly.

2. Without washing, transfer the slide to a glass of tap water for from three to five minutes.

3. Without washing, transfer to diluted Manson's stain for from twenty to forty seconds. One-half c.c. (7 drops) of Manson's stain to 50 c.c. of tap water in a Coplin jar gives

about the proper strength. This staining fluid in concentrated form keeps well, but the diluted stain should be freshly prepared each day.

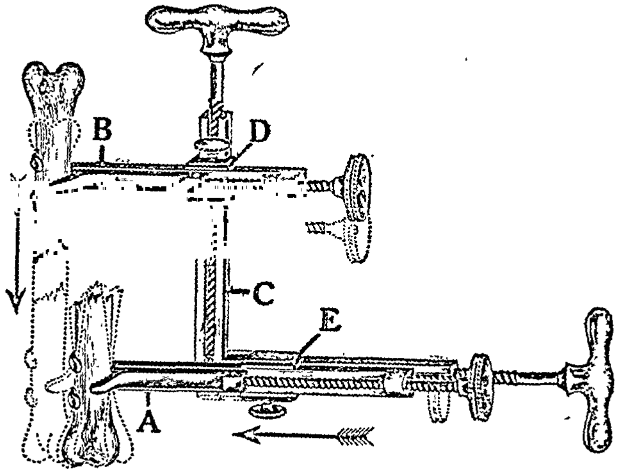
4. Wash quickly in tap water, dry and examine.

With this method, good preparations showing both the nuclear chromatin and the cytoplasm of the malarial parasite are obtained. The method is economical since very little of the methyl alcohol solution is used; and this is important in the tropics and at places far removed from the base of supplies. The slides being always in the vertical position, any precipitate which forms falls immediately to the bottom of the vessel. Soaking the slide in water during Step 2 does not affect the staining of the chromatin in the least, but does dissolve out most of the blue; this is replaced, however, in Step 3 by a better blue than any of the methyl alcohol stains are capable of giving. The whole point of the method, so far as malarial parasites are concerned, is that an intense cytoplasmic stain is added to the excellent chromatin stain obtained with Wright's, Leishman's, MacNeil's and other methyl alcohol stains, making the parasites much more distinct and more easily and quickly recognized in the routine examination of many slides for malaria.

APPARATUS FOR FRACTURED BONES

William E. Schroeder, M.D., Chicago

The instrument consists principally of three parts—an L-shaped arm, *C*, the two branches of which carry two carriages and two bone clamps. The removable carriages, *D* and *E*, are movable in two directions, one laterally and the other away from or toward the operator, as may be required. Mounted on the two carriages are two strong and adjustable bone clamps which are modifications of the well-known Lowman clamp.



Apparatus for holding and bringing into alignment fractured bones of the extremities, for the purpose of applying bone plates, splints of absorbable material or human bone grafts.

The illustration shows quite clearly the method employed in bringing the bone ends into apposition. The two bones are grasped by the clamps, *A* and *B*, these clamps then being attached to their respective carriages and held fast by means of heavy screws. Numerous anchoring points in the side of the clamps permit the thumb screw of holding the clamps firmly with but little exertion on the part of the operator. By means of a worm gear actuated by hand grips, each carriage with the clamp attached can be moved. Thus the bones can be brought into alignment no matter whether they override or in whatever position they may be. Immense traction can thus be had with very little effort, and once the parts are adjusted, they are held firmly together until plates, splints or grafts are applied or inserted. The instrument is made entirely of steel, and can be easily taken apart for sterilization.

PRACTICAL PHARMACOLOGY*

(*Continued from page 2067*)

XXV

ANTIEMETICS—GASTRIC SEDATIVES

This heterogeneous group, if it can be called a group, of drugs will be discussed briefly. The physiology of emesis which has been discussed in the preceding pages suggests the nature of those agents which may be used to lessen nausea and vomiting, for it is obvious that if emesis results from irritation of the gastric mucous membrane and from stimulation of the vomiting center in the medulla, emollients, demulcents, and other protective agents will lessen the local gastric irritation, and if relief is urgently demanded depression of the central nervous system may be resorted to, though this is seldom necessary, except as a temporary measure, for example, when it becomes necessary to prevent vomiting while administering a drug by the stomach.

Unfortunately, we have no drug which depresses the vomiting center without causing an undesired depression of other nervous centers.

Occasionally vomiting results from reflexes arising elsewhere than in the stomach and other measures than those just mentioned must be employed, for it is well known that foul odors and other purely psychic influences may cause nausea and vomiting. Psychic influences may contribute to gastric disturbances, or may prolong them even when they are not alone sufficient to induce actual emesis, and attention should be paid to such influences.

Heat and humidity in the atmosphere interfere with digestion and contribute markedly to nausea and vomiting when there may be another exciting cause.

Vomiting occurring after ether anesthesia usually ceases spontaneously after the mucus which has been swallowed is expelled but emesis occurs frequently when food is taken some hours after chloroform anesthesia. Hot water—not tepid—should be sipped, or a glassful may be drunk if small amounts do not give relief. Cracked ice is sometimes more serviceable than hot water. Thirst following chloroform anesthesia may be relieved by drinking hot water, when it is taken easily, but as this causes diuresis, which may or may not be indicated, and since the taking of rather large quantities of water tends to tax the stomach unduly, rectal injections of warm water may be used to avoid gastric irritation, warm water being retained better than cold.

Infants regurgitate milk without indications of gastric disturbance, when more than sufficient is taken, but when vomiting with distress occurs, due to gastric disturbances, it may indicate the need of substituting barley water for the regular food for a day or two.

When vomiting is secondary to diphtheria it is said to indicate cardiac weakness demanding urgent relief for the heart.

Vomiting occurs in nephritis and disturbances of other organs in which the stomach is not irritated directly, and if the emesis is severe and persistent it may call for sedatives for the vomiting center, in which case morphin may be injected subcutaneously.

---

* This is the twenty-fifth of a series of articles on useful drugs—on practical pharmacology for the general practitioner. As soon as completed, these articles, elaborated by additional subjects, will be published in book form.

Cyclic vomiting has been described as accompanying a variety of symptoms, and is probably not dependent on a single cause. Its treatment cannot be discussed here as the symptoms are too various and these call for separate treatment.

The vomiting of pregnancy often taxes the resources of the obstetrician, and occasionally it cannot be relieved by any means short of terminating the pregnancy. It would be profitless to enumerate all of the drugs which have been suggested for the relief of this symptom, for such a list would be little less than a catalogue of the materia medica. Hygienic and dietary measures appear to be the main dependence in such cases. Psychic influences play an important rôle in this condition. Cerium oxalate gained a certain degree of popularity in the relief of vomiting from this and other causes, but there is no evidence that it has any therapeutic value.

Nausea and vomiting which result from indigestion require rest for the stomach, which should be emptied by washing with a weak alkali if the vomiting does not suffice to remove mucus. A weak solution of sodium bicarbonate may serve the double purpose of dissolving the mucus and causing its removal by vomiting, when there is ineffectual retching.

When there is gastric catarrh, requiring protectives, bismuth subnitrate or subcarbonate may be used; these are preferably administered in the form of powders or mixtures and are not advantageously given in compressed tablets or even in the form of capsules. Acidity may be neutralized by lime-water, magnesia, or by a solution of sodium bicarbonate.

Depressants of the vomiting center include hydrated chloral, morphin and opium and cocain, and in fact, probably all hypnotics and general anesthetics.

EXPECTORANTS

The respiratory passages are lined with ciliated epithelium, and normally the secretions of the mucous glands are moved toward the mouth (or anterior nares) by the movement of the cilia, but when the secretions in the smaller air passages become excessive during inflammation, or when they become thick and tenacious, the cilia are incapable of effecting their removal, and coughing is induced. If the secretions become excessively viscid even coughing may be incapable of effecting their removal and it becomes necessary to liquefy them by increasing the secretion of mucus or by means of alkalies.

As previously stated, all nauseants increase the secretion of mucus, hence in practice we choose an agent which has a persistent nauseant action, with a minimum depressant effect on the central nervous system.

Antimony and potassium tartrate is absorbed very slowly from the gastro-intestinal tract, hence small doses suffice to induce prolonged nausea of slight degree, and it is commonly used in the form of a solution or the compound mixture of glycyrrhiza in the early stages of laryngitis and bronchitis when the secretion is usually scanty and the cough troublesome.

The choice of expectorants is often largely empirical; we do not know whether any of them stimulate the cilia to increased activity or not, and it has been suggested that some of them may act on the smooth muscles of the alveoli and terminal bronchioles in the lungs, increasing their peristaltic movements and forcing mucus accumulations into the bronchi, as the alveoli and the terminal bronchioles are not provided with cilia.

Many salts, including sodium chlorid, ammonium chlorid, and potassium iodid, increase the secretory activity of the mucous glands, effecting the liquefaction of the mucus through the alkalies contained in the secretions, and by diluting these with the increased fluids secreted.

It seems probable that the especial usefulness of ammonium chlorid as an expectorant may depend partly on the formation of very small amounts of ammonium carbonate in the bronchial mucous membrane, which is especially effective in liquefying tenacious mucus.

A cough which is merely sufficient to remove the secretions from the air passages does not call for treatment, but when there is considerable irritation with frequent coughing while the secretion is scanty, sedatives, such as codein, are indicated. In some cases it is desirable to increase the secretion by means of a nauseant while diminishing the irritation with a sedative to the point that the cough will just suffice for the removal of the secretion.

Patients frequently demand relief from cough when free secretion contraindicates interference.[1]

Excessive bronchial secretion may be lessened in various ways; atropin depresses the vagus endings in the glands; various volatile oils including the oils of turpentine, of cubebs, and of copaiba are sometimes used, but terpin hydrate has almost completely supplanted the volatile oils for this purpose. Balsam of Peru, benzoin, creosote and other irritants are used in this way.

Syrup of tolu and syrup of wild cherry are little more than vehicles, the hydrocyanic acid in the latter being present in the merest traces and without therapeutic effect.

The compound syrup of white pine of the National Formulary contains chloroform and morphin in addition to extracts of white pine, wild cherry, sanguinaria and other substances—a typical "shot-gun" mixture of nauseants, depressants of the respiratory center and stimulants of the bronchial mucous membrane.

Sore throat is best treated with gargles, sprays, or demulcents in the form of lozenges. A dilute solution of hydrogen peroxid is useful for cleansing the throat, or a hot 5 per cent. solution of potassium chlorate may be used as a gargle; to this may be added a few drops of solution of ferric chlorid. Small ulcers or areas of inflammation in the throat may be swabbed with cotton dipped in a mixture composed of one part of solution of ferric chlorid to ten parts of glycerin.

The official lozenges of ammonium chlorid are useful in treating sore throat but it is not easy to explain the effect of the ammonium chlorid in that case.. Lozenges of elm bark allay slight irritation of the throat.

There are few conditions in which self-medication and its unfortunate consequences are more common than in coughs and "colds," and there is a striking similarity between the composition of nostrums advertised to physicians in numerous medical journals and that of the patent medicines, so-called, which are advertised directly to the public. It is obvious that it matters little, so far as the consequences are concerned, whether the patient doses himself with Ayer's cherry pectoral or Jayne's expectorant, or has compound syrup of cocillana or glyco-heroin (Smith) prescribed for him by a physician.

---

[1] The following incident illustrates the unfortunate results of interference in such cases. A patient suffering from a cough with free secretion received a mixture containing morphin, and expressed his satisfaction at the prompt relief afforded. Later he felt greatly discouraged because (as he supposed) he had "caught fresh cold," which he attributed to his low resistance. In fact, the morphin suppressed the cough while the secretion continued, becoming purulent, and the necessary cough returned when the effects of the morphin had passed away.

DOSAGE

The nauseant dose of several of the emetics has been given. The dose of ammonium chlorid is commonly stated as from 0.3 to 1 gm. (5 to 15 grains) but it is much more frequently used in doses of from 0.15 to 0.2 gm. (2 to 3 grains). The troches of ammonium chlorid each containing 0.1 gm. (1½ grains) with extract of glycyrrhiza, tragacanth and sugar, flavored with tolu, afford a convenient form of treatment for sore throat. It may be prescribed for cough (laryngitis or bronchitis) somewhat as follows:

	gm. or c.c.	
Ammonii chloridi	5	+ʒ i
Syrupi acidi citrici..............	50	+℥ iss
Aquae....................q. s. ad	100	+℥ iii

M. Sig.: One teaspoonful every two or three hours.

Ammonium chlorid has a disagreeable taste which is disguised somewhat by the acidity of the mixture.

Ammonium carbonate is given in doses of 0.25 gm. (4 grains). Physicians sometimes overlook the acid character of syrup of squill and prescribe it with the strongly alkaline ammonium carbonate.

A nauseant and sedative may be prescribed together somewhat as follows:

	gm. or c.c.	
Codeinae sulphatis	0|5	+gr. viii
Syrupi ipecacuanhae	30|0	+℥ i
Aquae.... ....q. s. ad	100|0	+℥ iii

M. Sig.: One teaspoonful every two or three hours.

One should avoid the use of too much of the sedative in such cases, as this will lead to the total suppression of the cough. Terpin hydrate is given in doses of 0.12 gm. (2 grains) in powder, capsules or dissolved in elixir.

Many of the patent medicines, so-called, which are sold directly to the public, as well as those which are advertised directly to physicians, contain saponin derived from sanguinaria or other source, and a sedative such as heroin or morphin. No ready-made mixture is suitable for any considerable number of patients, because the doses of nauseants and sedatives should be adjusted carefully to the needs of each patient.*

ARSENIC

Toxic doses of the strongly ionizable inorganic compounds of arsenic cause gastro-enteritis with vomiting, diarrhea and abdominal pain, these symptoms being commonly delayed for half an hour or more. The first symptom frequently is a feeling of constriction in the throat with difficulty in swallowing. The evacuations are normal in appearance at first but later become watery and contain shreds of desquamated intestinal epithelium closely resembling the "rice-water" stools of Asiatic cholera. The fluid, unlike that of simple diarrhea induced by saline cathartics, consists of the serum of the blood, or it may also contain some blood, and this loss of serum results in a train of symptoms closely resembling those of actual hemorrhage. There is weakness, dizziness, headache, cold sweat and collapse. The features are pale and shrunken, the pulse weak, the respiration deep, later depressed. The symptoms are intensified until coma and death occur. Convulsions may occur (asphyxial) or they may be absent. The urine is commonly diminished or totally suppressed, because of the increased viscosity of the blood and the lowered blood pressure. Death may result from either circulatory or respiratory failure, that is, either the heart or the respiration may fail first, but when both are affected so profoundly each reacts upon the other, so that one cannot say that either alone is the cause of death.

The gastro-intestinal symptoms have been attributed to the local irritant action of arsenic, but they are now considered as the effects following absorption, and are explained in the following way: Arsenic causes paralysis of the walls of the capillaries, and later those of the arterioles, especially of the splanchnic region, rendering them more permeable than normally, so that there is a copious effusion of serum or even of blood, into the tissues. After the administration of very large doses of arsenic to animals one may observe extravasations of blood beneath large areas of the peritoneum. The escape of serous fluid raises blisters beneath the gastro-intestinal mucous membrane, and this is soon desquamated with the escape of large amounts of serum into the stomach and intestine, causing the "rice-water" diarrhea. The diarrhea and its attendant pain and loss of water cause a great fall in the blood pressure, and this is later augmented by the direct action of the arsenic on the heart, should the patient survive long enough for this action to take place.

Such serious disturbances of the circulation are always attended with corresponding depression of the central nervous system; especially is this true when the circulatory changes are induced suddenly. One has only to recall the frequency of dizziness due to interference with the cerebral circulation when one rises suddenly from a sitting or recumbent position, to appreciate that the great loss of serum in arsenic poisoning and the resulting circulatory disturbance must cause a variety of secondary effects.

If vomiting occurs early the symptoms may be of almost any degree of severity, because much, or comparatively little, of the arsenic may be evacuated thereby, dependent partly on the amount which has passed into the duodenum, or the poisoning may take on an extremely chronic character, even from a single dose.

There should be little difficulty in diagnosing chronic arsenic poisoning following the typical symptoms of acute poisoning, or where it is known that a large dose of arsenic has been taken, but the symptoms resulting from the repeated administration of very small amounts are often obscure and require patience for their recognition.

The symptoms of acute and chronic arsenic poisoning are detailed in almost all text-books of pharmacology and materia medica, and every physician should familiarize himself with these symptoms because of the frequency with which this type of poisoning occurs.

It will suffice for our purposes at present to enumerate some of the symptoms of the chronic type, merely to show the necessity for more careful study than it commonly receives. The symptoms are sometimes divided into three stages; in the first there is lassitude, loss of appetite, and there may be nausea and vomiting. This stage might lead one to suspect the presence of typhoid fever. The intestinal symptoms may be present, or they may be absent. In the second stage there may be symptoms resembling those of a "cold" owing to the irritation of the mucous membranes of the larynx and nose and of the conjunctiva. Various affections of the skin are described as occurring in this stage, including a typical discoloration or blackening.

---

* Owing to lack of space the materia medica of this group is omitted from The Journal. It will be included when this series is issued in book form.

In the third stage there are disturbances of sensation and motion in the hands and feet, and peripheral neuritis, together with numerous other manifestations which require careful consideration. The symptoms are not sharply marked off in the stages mentioned, but many of those commonly described as belonging to the second or third may appear earlier than this classification would indicate.

When vague symptoms lead one to suspect even the possibility of chronic arsenic poisoning the urine should be examined for traces of the metal. Of course one would not expect to obtain evidences of the poison by the grosser tests, but, on the other hand, the most delicate tests enable one to detect the faintest traces of arsenic in the urine. Such traces have comparatively little significance unless this evidence is supported by others of great weight, because traces of arsenic may be derived from foods containing it, either as a natural or as an added ingredient.

Chronic arsenic poisoning is attended with degenerative changes in the walls of the capillaries and later in the intestinal epithelium, and in various organs, including the heart, liver and kidneys.

Icterus results from the changes in the liver, and effusions occur in various tissues, that into the eyelids being usually early and fairly characteristic. The damage to the heart may fail to attract attention in the presence of other symptoms, such as nephritis, to which the attention may be mainly directed if the true cause of the trouble is not suspected.

The toxicology of arsenic is interesting from various standpoints. It played an important rôle in the crimes of professional poisoners in earlier times, and it is still employed occasionally for purposes of murder and suicide. It lends itself, unfortunately, to the poisoning of one member of a household by another when small doses can be administered frequently, because, owing to its tastelessness and lack of odor, it does not arouse suspicion and is all too easily obtained in the form of rat poison. All arsenic preparations which might be used in this way should be colored distinctively by the addition of lamp-black or indigo which cannot be mixed with most foods without attracting attention.

Fortunately, the metal can be detected in the vomitus, urine and feces, and in the cadaver long after death, so that it is probable that few adults die of acute arsenic poisoning without the fact becoming known.

The treatment of acute arsenic poisoning requires further investigation. It was accepted for many years as an established fact that as soon as possible after a poisonous dose of arsenic had been swallowed the patient should receive a large dose of moist ferric hydroxid, or preferably, the hydroxid with magnesia, which can be prepared more conveniently and quickly, when the materials are at hand.

Serious doubt has been thrown on the value of this procedure during the past few years, and the stomach should be washed out as promptly as possible whether the iron antidote be employed or not. Active catharsis should be induced with magnesium sulphate solution in order to remove any of the poison that has passed into the duodenum. Since prompt purgation is necessary in such cases, a large dose of the dilute solution of magnesium sulphate should be administered — preferably a pint of solution containing about an ounce of the salt. Naturally, purgatives are contraindicated after the intestinal symptoms have developed.

The elimination of arsenic depends somewhat on the way in which it is administered. When a toxic dose has been taken by the mouth the larger part may be evacuated with the vomitus, or with the washings of the stomach, and a large part of the remainder may be evacuated in the feces, especially if prompt purgation is induced. After absorption into the circulation arsenic may be found in almost all the body tissues. Elimination goes on very slowly indeed, so that months may elapse before it ceases to appear in the secretions, and some of it appears to be retained almost indefinitely.

A larger portion of the poison is said to be eliminated by the intestine after its oral administration, and a smaller part of the urine, but after the subcutaneous injection the kidneys eliminate more than the gastrointestinal tract. Diuretics should be administered after the subcutaneous injection of a poisonous dose if the patient is seen early, but caffein and theobromin will have little or no effect after the appearance of the "rice-water" stools because of circulatory disturbances previously mentioned; hence it would seem probable that the intravenous injection of a 2 per cent. solution of sodium sulphate, as mentioned in connection with strychnin poisoning, might be of benefit, but we are unaware of any experiments bearing on the subject.

The extraordinarily slow elimination of arsenic and its consequent tendency to accumulate in the body and to produce chronic poisoning are of especial interest in connection with the uses of arsenic in fabrics, and food preservatives.

A manufacturer of a food product used anilin to color it, the finished food as eaten containing about one part of arsenic in 20,000 million parts of food. He was probably unaware of the presence of arsenic in the anilin, and it would require about 1,000 tons of the food to furnish an amount of arsenic equal to a toxic dose for a man; nevertheless it was maintained that the practice was unlawful, though it could hardly be held that enough arsenic could be taken in that way to produce any perceptible effect in a life time, especially, as arsenic is frequently taken over long periods for its medicinal effect. Quite a different case was that of a manufacturer whose candy was found to contain six parts of arsenic per million. One pound of the candy contained as much as an average dose of arsenic for an adult, and its continued use in large amounts might very well cause symptoms.

In seeming contradiction to the preceding statement is the well-known fact that the administration of small and increasing doses of arsenic by the mouth leads to a higher degree of tolerance, apparently through an acquired resistance to absorption from the gastrointestinal tract, for such tolerant animals are not more resistant than others to arsenic administered subcutaneously. Remarkable stories of tolerance are commonly told of the arsenic eaters of the Tyrol.

As little as 0.1 gm. (1½ grains) of arsenic has proved fatal, but very much larger oral doses have been survived, and if vomiting occurs within less than half an hour after a fairly large dose has been swallowed the chances of recovery are fairly good, but of course one cannot depend on this alone, and other treatment should be institut [illegible] stated. There is an unfortunately [illegible] among the laity that larger doses of arsenic may be safer than smaller, but toxic ones. This is doubtless based on the fact that large doses do occasionally induce emesis in time to save life, while smaller doses may prove fatal.

In view of what has been said of the widespread use of arsenic in the arts, in medicine and in foods, with the consequent frequency with which at least small amounts may be taken without the knowledge of the patient, and the extreme slowness with which elimination takes place, it is obvious that the detection of traces of arsenic in the excreta or in a cadaver does not prove that observed symptoms or death resulted from arsenic in a given case, and one will understand the necessity of a careful study of the actions of arsenic before expressing opinions that may be of far-reaching importance.

The administration of small amounts of arsenic to young animals may cause them to grow more rapidly than other members of the same litter that receive the same food without the arsenic. Several observers found that the bones of the animals that received arsenic were longer and thicker than those of the controls; that their fur was glossier and other evidences of rapid development were also observed, but these effects are not always obtained and other investigators came to different conclusions with regard to the effects of arsenic on metabolism. Poisonous doses cause fatty degeneration in various organs, and other disturbances of metabolism.

Various explanations have been offered to account for the more rapid growth observed as the result of the use of arsenic, but it seems possible that the actions on the capillaries and the effects on the general circulation together with the stimulation of production of red blood corpuscles or of hemoglobin are concerned in the effects on metabolism.

It also seems possible that arsenic may serve to correct some adverse conditions entailed in those feeding experiments in which the greater growth was observed, for it does not seem probable that arsenic would influence growth favorably if the animals were kept under the best conditions of living and exercising in the open air. At least, no one would think of advising the routine administration of arsenic to healthy little children living under hygienic conditions.

Certain of the organic compounds of arsenic which ionize but little are much less active than the inorganic compounds that have been discussed. Cacodylic acid, which differs from arsenic acid by having two methyl groups in place of two hydroxyls of the latter, has long been known, the sodium salt having been introduced about fifty years ago. Sodium arsanilate was introduced into therapeutics in 1902 under the name of atoxyl under the mistaken impression that it was nontoxic. It exerts the arsenic action, though less violently than arsenic trioxid in equal weights, and in addition it is prone to cause blindness through atrophy of the optic nerve. When atoxyl was submitted to the Council on Pharmacy and Chemistry its composition was investigated, and it was shown that the arsenic is not present in the trivalent state as had been supposed, but in the pentavalent.

Following the introduction of organic compounds of arsenic, Ehrlich investigated a large number with the object of finding one capable of exerting the well-known trypanocidal action of the metal without the toxic action on the host, or at least of finding a compound in which the relative toxicity for the parasite and the host would permit of the administration of a single dose that would at once destroy all the micro-organisms in the blood.

As a result of this search Ehrlich and his co-workers brought out salvarsan, or arseno-benzol, more correctly called arsen-phenol-amine hydrochlorid. It has also been named "606" in reference to the laboratory number given the compound.

From the results of the early studies it was announced that a single dose of salvarsan was capable of destroying all of the micro-organisms of syphilis in the human body in suitable cases. It was also highly extolled in the treatment of various other diseases, including relapsing fever, and at the same time it was said to be relatively harmless to man in the dosage advised.

The literature relating to salvarsan is already enormous, and while it is not feasible to review this even partially, it may be said that a single dose apparently effects a complete cure only when it is given shortly after infection, if at all, and that it is far from being harmless, numerous deaths being undoubtedly attributable to its use even with the most careful technic.

Unfortunately, the spirochetes of syphilis may become more resistant than normal to arsenic after repeated doses, and it is usually necessary to combine the use of arsenic with that of mercury.

Neosalvarsan is a soluble compound of salvarsan thought by some to be tolerated better than the original product.

THERAPEUTIC USES

Arsenic trioxid is applied to ulcerated surfaces as an irritant, but its use is attended with severe pain. It has long been used in domestic practice and occasionally by physicians as a caustic for the removal of malignant growths, in the form of pastes. The action cannot be controlled accurately, it is very painful and there is some danger of the absorption of a poisonous dose when it is applied in this way. Its use is not recommended. It has long been employed and is still used as an application to ulcerated surfaces and by dentists for destroying the nerves in carious teeth.

It is used internally in a variety of disorders in which its mode of action cannot be explained satisfactorily. For example, it is used in neuralgia of a periodic character, and in chorea, in which it is of doubtful value. It is used in anemia, in which it probably stimulates the organs involved (bone marrow) to a more rapid regeneration of the red blood corpuscles or the hemoglobin. It is also used in pernicious anemia, in leukemia and in Hodgkin's disease (malignant lymphoma, or hypertrophic disease of the lymphatic glands of the body, attended with anemia). In these diseases its temporary effects are often markedly beneficial, but relapses almost invariably occur.

It is often used to improve the nutrition when the disturbance results from obscure causes, but, of course, it is not suited for use in all of those cases.

It has been recommended for use in diabetes, but like other drugs, it usually fails in that condition.

Arsenic is said to be useful in various skin diseases, such as psoriasis, lichen planus, chronic eczema, pemphigus, dermatitis herpetiformis, chronic urticaria and disturbances involving the sweat glands. It must be remembered, however, that the treatment of skin diseases by the general practitioner involves many difficulties because of the obscurity of the etiology in these conditions, hence they should be treated by dermatologists when they present unusual difficulties or conditions with which the practitioner is unfamiliar.

Attention has been called to the fact that the fur of animals used in experiments with arsenic was glossier than that of the controls, and horse dealers have long utilized this action of arsenic in improving the coats of horses. These results suggest the use of arsenic in man when there is faulty nutrition of the skin.

Acute inflammation of the skin contraindicates the use of arsenic.

The organic compounds of arsenic have a distinct field of usefulness in various diseases of protozoal origin, including sleeping sickness (trypanosomiasis), malaria, relapsing fever and syphilis, but the side actions, especially that on the optic nerve (with atoxyl), have greatly interfered with its use.

Arsenic has long been used in malaria, especially in the chronic forms which have resisted quinin, arsenic and quinin being commonly used together in those cases.

The cacodylate attained to some degree of importance many years ago when it was found that it exerts the actions of arsenic over a longer period than the inorganic forms and that it is less toxic.

Sodium arsanilate was used extensively for a time in the treatment of sleeping sickness but numerous cases of blindness resulted, and it has fallen into disuse for that purpose.

Salvarsan is widely used in the treatment of syphilis; it is given alone soon after infection or in combination with mercury in the later stages. It is also employed in the treatment of relapsing fever and in many other conditions, sometimes with good results, sometimes with harmful effects.

The results reported soon after the introduction of salvarsan raised hopes which subsequent experience proved were far too optimistic, but when the early literature has been discounted sufficiently we still have in it a valuable remedy.

Headache, nausea and malaise commonly follow the intravenous injection of salvarsan, the symptoms lasting for from twelve to twenty-four hours. Aside from these after-effects certain nervous effects have been observed. These symptoms — termed nervous relapse — are believed to be due to an increased activity of the spirochetes and they call for another dose of salvarsan or treatment with mercury.

Arsenic is sometimes used in the most diverse conditions including asthma, tuberculosis, bronchitis, leukemia, splenic anemia, and in numerous other diseases, and one is led to suspect that when improvement follows its use in those conditions it is merely a coincidence or that this improvement is attributable to the effects of arsenic on metabolism in general rather than to any direct effect on the diseased organs or the causes of the disease.

All forms of arsenic should be used cautiously or not at all in the presence of disease of the eye, especially of the retina, even if it be of syphilitic origin, because of its tendency to induce optic neuritis and blindness, but salvarsan is said to cause optic neuritis in few instances. Arsenic is contraindicated in severe cardiac and renal disease, and salvarsan cautiously used in syphilitic infants because of the danger from liberated endotoxins when the spirochetes are destroyed.

DOSAGE

For ordinary affections of metabolism or for a tonic influence arsenic trioxid is given in doses of from 0.001 to 0.002 gm. (1/60 to 1/30 grain). In diseases of the blood the dosage should be regulated according to the effect, but it is well to use as large doses as the patient will tolerate.

The various forms of inorganic arsenic are frequently administered in increasing doses until symptoms of mild intoxication appear. One may begin with 0.003 gm. (1/20 grain) of arsenic trioxid, three times a day, and increase by 0.001 gm. (1/60 grain) three times a day.

Solution of potassium arsenite and solution of arsenous acid may be given in doses of 0.2 c.c. (3 minims) three times a day, and increased by 0.05 c.c. (1 minim) three times a day. A slight toxic effect is indicated by nausea, colicky pains or a puffiness under the eyes. The presence of albumin in the urine may also be observed. Such symptoms may make it advisable to discontinue the administration of the drug for a time.

Solution of arsenous and mercuric iodids is usually administered in doses of 0.1 c.c. (1½ minims).

Sodium arsenate is given in doses of 0.003 to 0.005 gm. (1/20 to 1/10 grain) three times a day and increased as with other preparations of arsenic.

Of the organic combinations of arsenic, sodium arsanilate, (atoxyl, soamin), is given in doses of 0.02 gm. (1/3 grain) gradually increased, and sodium cacodylate may be given in doses of 0.03 gm. (½ grain). The former of these two products is used only by injection; the latter is frequently administered hypodermically though it may also be administered by mouth.

The dose of salvarsan is 0.5 gm. (7½ grains). Since it is not suited for oral administration it must be given intravenously, subcutaneously or intramuscularly, but intramuscular injections have been followed in several instances by the toxic effects of arsenic; furthermore, the intramuscular injection is painful and is usually followed by a painful inflammatory nodule which persists for some time. It is seldom employed by those who have mastered the technic of the intravenous injection and no one should undertake to administer salvarsan intravenously without having mastered the somewhat difficult technic.

Salvarsan, being acid, is neutralized and suspended in a neutral fluid for subcutaneous or intramuscular injection. A clear solution in sterile alkaline fluid is used for intravenous injection.

The powder decomposes rapidly on exposure to the air, and suspensions and fluids intended for injection should be used at once. If any part of the contents of a tube remains unused when a dose is administered it should under no circumstances be mixed with a subsequent dose but should be thrown away. Even those tubes that are cracked before being used, permitting the action of the air, should be rejected. The water used for making intravenous injections should be distilled shortly before being used. Various forms of apparatus are advised by different authorities, but most of the apparatus employed for the injection can be had in any first class pharmacy or instrument maker's shop.*

(To be continued)

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 North Dearborn Street . . . Chicago, Ill.

Cable Address . . . . "Medic, Chicago"

Subscription price . . . . . Five dollars per annum in advance

Contributors, subscribers and readers will find important information on the second advertising page following the reading-matter

SATURDAY, JUNE 26, 1915

On account of the large amount of space occupied by the Index in this issue of The Journal, certain departments have been omitted entirely and others abbreviated. The distance from The Journal office of the place of the annual session, together with the fact that this is the last number of the current volume, makes it desirable to omit the publication in this issue of any of the minutes. An effort will be made, however, to present in the next issue — July 3 — a complete report of the proceedings of the session.

THE INDEX

This issue of The Journal contains the index to the current, or sixty-fourth volume of The Journal, including the current medical literature which has been listed from week to week. Original articles in the leading medical journals of the United States and the principal foreign countries are included under the latter head.

In the author index appear the names of all who have contributed articles to The Journal or to any other journal listed in the current literature department, and the names of those whose papers are abstracted in the medical society reports in The Journal. In the subject index are complete references to all reading matter in The Journal, and references to original articles in all the domestic and foreign journals listed. To facilitate the use of the Index, not only are titles arranged under the subject of the article with double entry when necessary, but also there are numerous cross-references. The figures in boldface type refer to reading matter in The Journal.

The Index appears in pamphlet form[1] under the title "Guide to Current Medical Literature." This pamphlet contains, in addition to the author and subject indexes published in this issue of The Journal, the titles of the articles listed, arranged chronologically and by journals, as in the Current Medical Literature department. It is issued in separate form for convenience — to make it unnecessary to handle the bound volume of The Journal.

Just preceding the Index is a list of the journals indexed during the past six months. Any foreign journal, except those preceded by a star, will be lent by The Journal to subscribers and Fellows of the American Medical Association in the United States, with the understanding that such journal will not be retained by the borrower over three days. Requests for journals should be addressed to the Library of the American Medical Association, and six cents in stamps should be enclosed to cover the average expense of mailing. No domestic journal will be lent, as these can be obtained direct from the publishers as easily and as quickly as from The Journal. The addresses of the domestic journals are given.

It will be noted that in the Index in this number of The Journal there is a marked increase in the number of headings devoted to war subjects. The words "soldiers," "war," "army," "wounded," "wounds," "typhus," "tetanus," etc., are followed by numerous references occupying from three to ten times the amount of space devoted to them in previous indexes.

FOURTH OF JULY ANTICIPATIONS

The conflagration in Europe modifies all American events, and it will be of interest to observe its effect on our annual mimic warfare of July 4. Will the general depression of spirits and resources reduce the amount of explosive exuberance, or will the increased familiarity with gunpowder and bloodshed increase our notorious contempt of human life and suffering? The Journal has collected statistics on the injuries of the Fourth for twelve years, and the curve is now well enough established to indicate very clearly the annual extent of the old-fashioned celebration. Last year, for some unexplained reason, there was a slight increase in the total number of accidents and deaths, there being 1,506 accidents and forty deaths in 1914 as against 1,163 accidents and thirty-two deaths in 1913. Of the accidents last year, Pennsylvania with 487 and New York with 250 accounted for nearly half the total Independence Day devastation of the country, and it is in these two states especially that improvement must be made. Since The Journal first began to compile these statistics, Pennsylvania has always led in the number of accidents, usually by a wide margin. It has been suggested, perhaps facetiously, that this is the outcome of the possession of the Liberty Bell and the traditions of the Cradle of Liberty; if so, there is naturally a doubt whether the possession is worth the price. It has been certainly demonstrated that a community which wishes to free itself from this sort of destruction of person and property can do so. Not a few large cities have found it possible to pass through the Fourth without a single accident. It follows, then, that the number of Fourth of July accidents is the measure of the effort made by a community to rid itself of this long-suffered nuisance.

---

[1] The Guide to Current Medical Literature may be obtained from the Association office at 50 cents a copy.

This year one factor may make for an increased number of accidents — the occurrence of the Fourth on Sunday, which results in two days of celebration in many communities. We must, therefore, be prepared to do our part in reducing the number of fatalities from these accidents. The reduction in the total number of deaths from tetanus to three in 1914, as compared with 150 cases in 1909 and 417 in 1903, is far out of proportion to the reduction in the number of accidents from which tetanus might have resulted. This indicates that the medical profession has learned how to prevent this most frightful sequel of injuries, and is fully alert to the dangers that reside in Fourth of July wounds. The European war has demonstrated on a hideously large scale the frequency of tetanus in unclean wounds and the great value of tetanus antitoxin in prevention, especially when its use supplements adequate surgical cleansing of the wounds. The importance of this point need not be dilated on, as was necessary twelve years ago, when neither the danger of tetanus nor the efficacy of antitoxin as a prophylactic was generally recognized. The same may be said of the intraspinal injection of tetanus antitoxin in developed cases of tetanus. This is now a recognized procedure which unquestionably gives results far superior to those obtained by any other method of treatment. At the recent meeting of the Association of American Physicians in Washington, Nicoll reported that of twenty patients treated in the New York City Department of Health by intraspinal injection of antitoxin, there had been but four deaths.[1] Improved results have also been reported from the military hospitals of Europe from the intraspinal administration of tetanus antitoxin.

It may be well also to repeat the instructions outlined a year ago,[2] for the prophylaxis of tetanus in Fourth of July injuries:

1. Carefully and thoroughly remove every particle of foreign matter from the wound, laying it open; an anesthetic should be given if necessary.
2. Dry the wound thoroughly, and paint it and the surrounding parts as carefully as possible with iodin, or else cauterize it thoroughly with a 25 per cent. solution of phenol (carbolic acid) in glycerin or alcohol.
3. Apply a loose wet pack, using a solution of some such antiseptic substance as boric acid or alcohol.
4. As soon as possible inject intravenously or subcutaneously 1,500 units of antitetanic serum and continue the injections if indications of possible tetanus arise.
5. In no case close the wound. Allow it to heal by granulation. Remove the dressings and packing each day and apply fresh ones.

VACCINE THERAPY IN TYPHOID FEVER

It is difficult to arrive at a just estimate of the value of vaccines in the treatment of typhoid fever, because the evidence for and against their use is derived from two widely different sources. From a theoretical standpoint, such a procedure has little justification. It is well known that there is an extensive invasion of the blood by the infecting organism early in the course of the disease, and it seems reasonable to assume that these invading organisms furnish sufficient antigenic stimulus to cause the maximum antibody formation. On the other hand, if this antibody formation is delayed early in the course of the infection, vaccines may be of value in stimulating such a response. In the field of clinical medicine, many observers have reported striking results from the use of vaccines, and it is the common opinion of these clinicians that they are efficacious in the treatment of typhoid fever.

The clinical data in the literature pertaining to this phase of the treatment of typhoid fever have recently been reviewed by Krumbhaar and Richardson[1] of Philadelphia. This analysis includes more than 1,800 cases, and in 95 per cent. of these, favorable results were observed. Thirty-five of the thirty-nine observers concluded that the vaccine was useful as a therapeutic measure. In almost all instances, the course of the infection was favorably influenced, and in many series the mortality was reduced. In a series treated by Petrowitch, the mortality was 3.2 per cent., as compared with 8 per cent. in 220 unvaccinated patients. Krumbhaar and Richardson used vaccines in the treatment of ninety-three typhoid patients in the Pennsylvania Hospital during the past three years. Their results were so promising that they consider the use of vaccines an important procedure in the routine treatment of the disease. The symptoms were rarely altered beyond a transitory rise in temperature; but relapses and complications were diminished in frequency, and when vaccine treatment was instituted early in the course, there seemed to be a favorable influence exerted on the intensity of the infection. Since agglutination is often absent during the first two weeks of the attack, these investigators assume that antibody formation is often delayed, and that by the use of vaccines an early activity of this process can be brought about. The experiments of Gay and Claypole also suggest that there may be a hyperleukocytosis following the injection of a vaccine during the course of typhoid fever. Should these experiments receive confirmation, a good theoretical basis would be afforded for vaccine therapy in typhoid.

The type and dosage of the vaccine have had no apparent influence on the results obtained. Sensitized vaccines have been strongly advocated by Besredka,

Metchnikoff, Garbat and others, and on theoretical grounds such vaccines would be favored; but the majority of investigators have had good results with suspensions of dead bacteria prepared according to Wright's method. Although autogenous vaccines generally have been preferred, stock vaccines prepared from organisms selected for their high agglutinogenic power have been efficacious in the hands of many. Reports, however, have been so uniformly favorable with all preparations, that it seems as if the type used is of secondary importance. The dosage has also varied widely with different investigators. Semple, Waters, Petrowitch and others used small doses, while Foster, McArthur, Fletcher and Meakins obtained equally good results with large doses. Krumbhaar and Richardson gave 500 million as an initial dose and two or three larger doses at short intervals. They conclude that their results were more favorable in the cases in which large doses were given. The dosage, however, must be gaged by the general condition of the patient. When the patient is very toxic, only small amounts of vaccine can be used with any degree of safety. Previous mention has been made of the remarkable results obtained by Ichikawa from the intravenous injection of sensitized vaccines.[2] Using this method of inoculation, he was able to produce a rapid drop in the temperature to normal and often an early recovery. In his cases, mild intestinal hemorrhages occurred in a few instances following the injections; but these hemorrhages were no more numerous than in the unvaccinated patients. Subsequent investigators[3] also report favorable results from the intravenous method of administration of the vaccine, but they strongly emphasize the danger of a severe general reaction in some instances. Signs of collapse, severe diarrhea and intestinal hemorrhages are complications which have occurred simultaneously with the rapid fall in temperature, and in a few instances there was an unfavorable termination. The ultimate value of this method of administration of vaccines, therefore, is a question which further observations must determine.

Including the recent encouraging reports of Goldscheider and Aust,[4] Rhein[5] and others, the clinical evidence now at hand is derived from careful observations on about 3,000 cases of typhoid fever treated with vaccines. In almost all instances, it seems that some degree of favorable influence could be noticed from their use. The observations of Elmer[6] indicate that vaccines will not prevent the attack, once infection has begun; but it seems probable that their use early in the course of the disease modifies the duration and intensity of the attack. Furthermore, in complications, especially localized typhoid infections such as periostitis and cholecystitis, and in the treatment of typhoid carriers, vaccines are of limited value. In local infections in which there is a secondary invading organism, as in pneumonia and otitis media, typhoid vaccines are probably contraindicated.

Careful bacteriologic and serologic study is an essential prerequisite to vaccine therapy, which requires an exact etiologic and early diagnosis. Before the question of the efficacy of this form of treatment can be settled fully, the mechanism of the action of vaccines in generalized infections needs to be better understood; obviously, this is a problem in the field of experimental medicine. In the meantime, the results at hand, which indicate that, used with discretion, vaccines not only do no harm, but also may be of benefit, should stimulate to further and careful observations.

THE URINARY PROTEIN OF NEPHRITIS

It is conceivable theoretically that the protein present in albuminous urine is derived from the kidney or from the blood through damage to the capillary wall, or is a specific protein distinct from that derived from either the renal tissue or the blood. According to Fischer's widely discussed views, the urinary protein is derived, in part at least, from the renal cells, from which it has been dissolved under the influence of acids.[1] In connection with a current belief that the urinary protein found in nephritis represents serum protein rather than tissue protein, we referred some time ago[2] to the experiments of Salus,[3] who attempted to solve the question by the use of modern serologic or biologic immunity reactions. The technic in this field has become so refined that different proteins from the same animal may possibly be distinguished, and it therefore seemed likely that the controverted questions of the origin of the proteins of nephritic urine could be reached in the same way. Salus prepared a so-called organ plasma, a solution of tissue proteins obtained after completely removing the blood from various organs by Pohl's method. He found that such an antigen is entirely distinct from the antigens of the blood. More specifically, Salus took up the question of the origin of the protein in nephritic urine, and summarizes his results as follows:[4] Antiserum for human kidney contained neither precipitins nor complement-binding antibodies for either human serum or nephritic urine; hence the latter does not contain the antigens characteristic of kidney tissue. Guinea-pigs sensitized with nephritic urine or blood serum did not give anaphylaxis reactions with kidney plasma, and animals sensitized with this plasma were reactive to serum or urine only when the plasma gave distinct reactions for blood. He therefore concludes that the protein of nephritic urine must be serum protein, and not renal tissue protein.

[2] A Controverted Theory of Nephritis, Current Comment, THE JOURNAL A. M. A., June 20, 1914, p. 1971.

[3] Salus, G.: Biologische Versuche mit Organplasma, Biochem. Ztschr., 1914, lx, 1.

[4] We quote from a review by Cameron, A. L., and Wells, H. G.: The Origin of the Proteins of Nephritic Urine, Arch. Int. Med., May, 1915, p. 750.

As these biologic reactions seem to offer the greatest promise of success in determining the identity of individual proteins, The Journal stated editorially that they place the burden of proof on those who maintain that the urinary protein of nephritis is merely the dissolved contribution of kidney cells subjected to an abnormal environment, rather than escaped blood components.

In criticism of these comments, Fischer[5] remarks that Salus concluded correctly from his experiments that the protein in the urines examined by him contained blood proteins. Fischer adds that no one has ever disputed this fact, for hemorrhage through gross rupture of the blood vessels and by diapedesis is common in all types of nephritis. With reference to the failure to obtain reactions indicative of dissolved kidney protein in the urine, Fischer remarks:

> In the face of the fact that it is difficult to prepare a specific antiserum even when kidney substance is used directly, such findings are hardly conclusive. The colloid chemists, moreover, know how alterable in consequence of mere laboratory handling are the reactions of proteins, and so some argument will be necessary to make those of solid organs and of organ extracts synonymous in their minds. Salus himself recognizes these difficulties.

A much more trenchant critique, pointing out the meager and variable character of Salus' fundamental experiments, has been published recently by Cameron and Wells.[6] They are quite unwilling to admit the conclusions of Salus on the basis of what they regard as inadequate proof. In a new attempt to secure further evidence on the disputed points relating to the origin of the urinary protein, these Chicago investigators note that part of the contradiction presumably depends on the difficulties inherent in the available methods for distinguishing, even by the biologic reactions, between different proteins coming from the same animal. A series of experiments by the anaphylaxis method gave no evidence of the existence of antigens in either urine or kidney distinct from each other or from the antigens of human serum. This result, as Cameron and Wells remind us, does not answer the question of the origin of urinary protein, but merely indicates the inadequacy of the anaphylaxis method for the solution of the problem. In fairness, therefore, the questions involved therein must frankly be regarded as still open for review.

DISEASE RESISTANCE IN PLANTS

In matters of health and disease, all living things have intimate relations. The factors that increase resistance to disease in plants can scarcely fail to interest physicians. Probably at least suggestive if not directly valuable hints for the prevention or inhibition of the contagious infections in human beings can be derived from a knowledge of the natural processes by which plant resistive vitality is encouraged. There is, too, a definite assurance that certain serious human diseases—tetanus and the gas-producing bacillary infections—are caused by micro-organisms fostered by plant life, and more than a suspicion that further study may reveal other similar relations.

Dr. Otto Appel[1] has considered the analogies between plant and human diseases, and the problem of resistance. The question of alternation of hosts for certain diseases is a plant as well as a human pathologic feature. The tapeworms and echinococci require an intermediate animal host, and prevention is much easier when the relations between the hosts of the two stages can be regulated. When rust appears in a pear orchard, the danger may be removed by eliminating all juniper trees from the neighborhood, the juniper being the host for the alternate stage of the fungus. The same measure must be adopted to assure prevention in the case of red rust of wheat in countries in which the fungus does not reinfect the wheat directly, but grows in the spring on the barberry. This serious scourge has practically disappeared from Germany since the removal of all barberry and mahonia bushes from districts in which wheat is grown.

Dr. Appel declares, in words familiar to physicians of human maladies, that it is more difficult to cure a plant already diseased than to prevent the disease. Only in rare cases is the method of "cure" known. Plants are not organized like animals, and in most cases it is impossible to influence a central system. Even with that possibility, physicians find "cures" difficult enough. Some of the adjuvants in the treatment of disease in plants are suggestive of phases of our medical problems. The cure of fungous diseases of different trees by giving the roots an abundant water supply is an example of treatment based on the principle that "many fungi are unable to grow in tissues which show a high water pressure. In dry soils the water content is kept on a low basis, and this favors the attacks of the fungus." Observant physicians have found this principle, so useful in limiting plant disease, of great value in the treatment of affections due to the growth of low plant life in the human intestines. A dry diet often seems to favor putrefactive processes, while the free taking of fluids not only affects constipation favorably in a mechanical way, but also lessens the growth of disturbing micro-organisms in the intestines.

---

[1] Appel, Otto: Disease Resistance in Plants, Science, May 28, 1915.

More important still is the securing of varieties of disease-resistant plants. The method has long been understood, but the application of the principle is only now being successfully applied. The plant specialists, however, are much farther advanced in the solution of their problems than are the eugenic specialists. Of the different species of wheats, the difference in resistance to various serious affections is very marked. As a rule the Western European varieties are resistant, while many of the Eastern varieties are liable to rust. In both regions, however, there are marked exceptions, and the plant found in Palestine some years ago, which has sometimes been regarded as the ancestor of our common cultivated wheat is, curiously enough, a nonresistant species, showing by its survival that individual vitality may surmount dangers that would seem inevitably to doom a plant variety. The subjection to certain diseases of the plants of a region hitherto spared the special contagion is sometimes followed by serious devastation among crops. The corresponding incident in human beings was well illustrated by the ravages of smallpox, of tuberculosis and even of measles among the American Indians when these diseases were first introduced on this continent by the Europeans. Nature has gradually selected the disease-resisting varieties among human beings, so that a certain immunity has developed among peoples long subjected to the contagion of particular diseases.

From a chemical standpoint, the facts concerning plants are suggestive to the student of human disease and immunity. Dr. Appel says:

> A glance at sugars and acids shows that these substances also exert an influence in disease resistance. The presence of benzoic acid in *Vaccinium vitis idaea* is supposed to be the cause of its resistance to fungous diseases. In the same way the tannins have a relation to resistance. This was shown by Behrens in his work on fruit decay, and confirmed by Cook and Taubenhaus. On the other hand, sugar favors the growth of fungi, as is shown clearly in the case of apples and pears. Henneberg even claims immunity for some varieties of potato from certain diseases on account of their high sugar content, but this has not been established beyond doubt.
>
> Finally, the enzymes exert a definite influence on immunity, the oxydases taking the lead. These ferments work directly or indirectly by producing resistant chemical substances.

Everywhere in nature, similar forces are at work, and the same problems must be solved. The outlook for a solution of the involved questions of disease resistance and immunity is more promising when it is seen that many scientific investigators are working from different sides. The most important development of modern biology came when the great principle of the existence of cells was transferred from botany to zoology by Theodor Schwann at the beginning of the nineteenth century. When Virchow took the further step of applying the cell doctrine to pathology, he made perhaps the greatest advance in modern medicine. He used to declare in later life that when these two far-reaching developments were made by himself and Schwann, the rising generation of scientific investigators in Germany were quite as much interested in botanic problems as in microscopic anatomy. It was this breadth of interest, he declared, that gave them the larger outlook which enabled them to look beyond the bounds of what had been hitherto known to newer phases of knowledge.

SOME FACTS ABOUT INSENSIBLE PERSPIRATION

However varied and important the physiologic activities of the skin may be, they usually receive scant consideration in treatises on the functions of the body or in so-called systems of medicine. This is unfortunate for many reasons, and particularly because it tends to inculcate a sort of disregard for certain properties and performances which are peculiar to the cutaneous surfaces and not without significance in medical practice. The sensory nervous mechanism involved in the covering of the body plays a highly important rôle by rendering us appreciative of our environment and responsive to a variety of influences that are wont to react on us. Much of our life of sensation is bound up with the structure of the skin, and many of our reflexes are initiated in relation to it.

These are only a few incidents in the functions of the skin. Its participation in the regulation of temperature all too often lacks appreciation, if one may judge by many misguided practices which are current in connection with the hygiene of clothing and ventilation. Although the sweat glands were discovered by Malpighi[1] as early as 1687, it required a rediscovery[2] of them in man in 1834 to direct attention to the functional possibilities which the secretion of water on the external surfaces of the body actually presents. Even then for some time doubt remained as to whether the glands are concerned with a specific output of water rather than with such activities as the sebaceous glands are now known to represent.

Ever since the days of Sanctorius (1614) the expression "perspiratio insensibilis" has been in use. For him it represented essentially the loss of body weight which could not be accounted for by the visible and weighable excreta. In part this loss obviously is due to a removal of water through pulmonary respiration, together with the excess of exhaled carbon dioxid over absorbed oxygen. There remains for consideration the losses through the skin, some of which become apparent in the form of sweat.

Can water be lost through the skin in any way other than by the mechanism of the sudoriferous glands? Is there a true insensible perspiration represented by a purely physical transport of water through the skin into the surrounding medium? Of course it has long been recognized that even where no visible drops of sweat collect on the cutaneous surfaces, water may be, and usually is being, vaporized from them. It is quite conceivable, however, that in such cases evaporation may keep pace with sweat production and thus give an impression of insensible perspiration without the intermediation of the cutaneous glands.'

---

[1] Malpighi: De externo tactus organo, in his Opera omnia, 1687, pp. 203, 208.

[2] Brechet and Roussel de Vauzeme: Ann. d. sc. nat., 1834, ii.

The longstanding uncertainty respecting the origin of water imperceptibly eliminated from the skin was dispelled by a series of observations on human individuals in whom an unusual anomaly of this organ exists. Loewy and Wechselmann[3] have had the exceptional opportunity of studying subjects in whom a defective development has resulted in complete absence of skin glands, so that both sweat and sebaceous secretion were lacking. Here, then, it became possible to investigate the occurrence of loss of water from the skin independently of sweat formation. It was found that such sweat-free persons may experience considerable output of water through the skin. The variations of such a process of elimination are considerable. The quantity may reach 600 grams of water per day for the entire body. This represents a true insensible perspiration — a diffusion of water vapor — following definite physical laws.

The observations made in these unique cases representing, it may be noted, persons having ties of blood relationship and thus exhibiting a hereditary factor in their common skin defect, supplement the facts learned from normal individuals. As a result of the different investigations,[4] it is concluded that the physical loss of water varies greatly in different parts of the body — a fact only recently verified by Galeotti and Macri[5] at the University of Naples. They found the insensible perspiration to be greatest from the surfaces of the hand, somewhat less from the neck and cheeks, and still smaller in relation to the chest and back. According to Galeotti and Macri there is a correspondence, in some parts of the bodies of normal individuals, between the number of the sweat glands and the extent of evaporation from the skin. The parallelism in this respect is, however, by no means complete, so that there is no justification for assuming that the water evaporated is derived solely from sweat glands. Loss of water evidently also takes place through the epidermal layers of the skin, precisely as in the case of the sweat-free subjects of Loewy.

The temperature of the environment often exerts an influence on the evaporation from the cutaneous surfaces in the sense that with increased external temperature the degree of insensible perspiration is augmented. This is, however, not uniformly the case, according to Loewy.[4] He regards the condition of the skin as decisive for the extent of loss of water. With the same external temperature the output will vary with the momentary make-up of the skin, so that it is not regarded as extreme to attribute any influence of the external temperature to its more immediate effect on the cutaneous organ as a whole. In febrile patients the output of water is always greater than in the case of healthy persons.

So far as the loss of water by purely physical processes is concerned, the temperature of the surface layers of the body is the factor of chief importance.

Current Comment

HOW DOES URIC ACID EXIST IN THE BLOOD?

Novelties in the domain of uric acid chemistry and physiology continue to attract attention. Some recent studies by S. R. Benedict[1] of the Cornell University Medical College, New York, he believes, indicate the existence of uric acid in at least two forms of combination in the circulating blood. One part is "free" and represents the quota ordinarily determined by the current procedures for the estimation and separation of uric acid in the blood. In addition to this, Benedict has shown that vigorous treatment, such as is represented by hydrolysis with strong hydrochloric acid, makes it possible to obtain a decidedly larger yield of uric acid. This is taken as an indication of a "combined" uric acid. When ox blood, which has been the chief object of study, is allowed to stand in the presence of a preservative, it shows a marked and rapid increase in the "free" uric acid, with a corresponding decrease in the "combined" uric acid. This strongly suggests the possibility of enzyme action leading to a liberation of uric acid from some more complex combination. The magnitude of the different types is indicated by the figures obtained for ox blood, namely a "free" uric acid content of 0.5 mg. per hundred c.c., and a "total" uric acid content of about 7 mg. Perhaps even more surprising is the report by Benedict[1] regarding the distribution of uric acid between the serum and corpuscles. The results show that it is contained quantitatively in these formed elements. The serum seems to be devoid of traces even, in the case of the ox. This is not true in the case of birds, in which, on the contrary, it is present in the serum alone. One must remember, however, that uric acid plays an entirely different rôle in the metabolism of birds, in which it functions as the characteristic and preponderant end-product of nitrogenous metabolism. The facts alone deserve to be cited. According to Benedict, in ox blood the uric acid is for the most part, if not wholly, in combination and within the corpuscles; while in chicken blood, the uric acid circulates free and is contained in the serum. These findings, if they do not represent some subtle perversity of analytic procedure, call for extensive investigation. Concerning the nature of the alleged combination, the statement is made that it is certainly not protein in nature. If we repeat Benedict's very tentative hypothesis that uric acid, which can be further catabolized, exists in combination in the organism, while that which is to be eliminated as such circulates in the blood in the free state, it must be done with circumspect reserve. This has long been a favorite field for theorizing; and speculation should be subservient to experiment.

FACTS ABOUT RATTLESNAKE VENOM

Although rattlesnake poisoning has lost most of its former prominence as a cause of death in the United States, the toxic agent itself continues to be a source of scientific interest. Certain points in regard to its action have been debated. Thus it has been asserted[1] that the venom of the rattlesnake is toxic to this species itself. Recently, however, Welker and Marshall[2] of the Robert Hare Chemical Laboratory at the University of Pennsylvania, Philadelphia, have injected the fresh poison obtained directly from the living animal intramuscularly into the same species, *Crotalus adamanteus,* without detecting any untoward effects on the snakes. Rattlesnake serum may be somewhat toxic to certain laboratory animals, but not more so than is the serum of other species. It is said that snake venom exhibits little if any toxicity when it is administered by way of the alimentary canal. This has led to the assumption that the bile exerts antitoxic properties on it. Fraser,[3] for example, believed that snake bile had a marked antitoxic action on the venom—an effect exhibited likewise by ox bile in a less marked degree. Welker and Marshall[2] have found that the bile of the rattlesnake is not highly toxic for pigeons, with which they experimented; but they failed to demonstrate the slightest antitoxic power in this secretion.

COAL-MINE FATALITIES

Nearly three quarters of a million men are at present engaged in the work of coal mining in the United States. The hazards of their occupation are familiar to every newspaper reader. Many persons fail to realize, however, that aside from the shocking accidents which come prominently into the public notice there are numerous causes of death which are not so often brought to the attention of the world at large. The loss of life in the coal mines is largely due to accidents underground, nine tenths of all the deaths being located there. Most of these are occasioned by falls of roof; many by mine cars and locomotives, by gas explosions and burning gas, and by coal-dust explosions; in lesser number are the underground fatalities by explosives, electricity and diverse other causes. About one tenth of the deaths occur in connection with the shafts and on the surface. In recently published statistics[1] the Bureau of Mines notes that the fatalities in coal mines in the United States in 1914 were 334 less than during the preceding year, the total fatalities being 2,451 as compared with 2,785 for 1913. The saving of one life every day in the year in any industry deserves more than passing notice. The principal causes of fatal accidents that show a material decrease were coal-dust explosions, 96 per cent., haulage 11 per cent., and falls of roof and pillar coal 10.6 per cent. These lower rates cannot be attributed to any single influence. They may, however, be assigned in part to any of the following agencies: closer and more careful inspection by the state inspector; better enforcement of laws and regulations by the operators; the miner's realization of the dangers attending his daily work, and his efforts to reduce accidents, because of the educational campaign conducted in his behalf; the more general use of safety lamps in doubtful mines; the use of permissible explosives; humidifying dusty mines; first-aid and rescue training in accidents which saves lives that might otherwise be lost; the enactment of industrial accident compensation laws and, last but not least, the spirit of cooperation on the part of all concerned. The growing evidence of the progress being made by modern industrial hygiene, even in fields in which inroads have been difficult, is a gratifying sign of the times.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

GEORGIA

Hospital Incorporated.—A petition has been made to the superior court of Screven County for the incorporation of the Screven County Hospital in Sylvania. The capital stock of the institution is to be $15,000.——The superior court of Tift County has received a petition for the incorporation of the Tift County Hospital at Tifton. The purpose of the corporation is charitable and is not organized for individual pecuniary gain.

Hospitals Dedicated.—The hospitals of the University of Georgia, Augusta, were dedicated June 1. The buildings, three in number, have been erected at an expenditure of about half a million dollars. The dedication exercises, which were held in the building, consisted of the presentation of the hospital by the mayor, the acceptance on behalf of the faculty by Dr. William H. Doughty, Jr., dean of the medical college, and an address by the Hon. J. C. C. Black, who paid an eloquent tribute to the physicians and nurses.

Hookworm Campaign.—The state is conducting a systematic campaign against hookworm, with the assistance of the Rockefeller Foundation. It has been decided to carry on the work in future by county organizations and already a number of counties have begun the work. Free examination and free treatment have been provided in a number of counties, and already a large number of persons have taken advantage of this arrangement. That hookworm is not the only parasitic disease prevalent is shown by the examinations of Dr. Charles R. Henry, Atlanta, and J. R. Webb, an assistant, in Gatoosa County, where among 550 persons examined forty-one were found to have hookworm, forty-two ascaris and thirteen pinworm.

[1] Fay, Albert H.: Coal-Mine Fatalities in the United States, During the Calendar Year 1914, Bureau of Mines, March, 1915.

Personal.—Dr. Harry Rubin, Savannah, has been appointed house physician of the Fresh Air Home, Tybee.——The faculty and adjunct faculty of the Atlanta Medical College, which is to be merged next fall with the Emory University, gave a dinner, June 7, in honor of Dr. William S. Elkin, for many years dean of the college, at which a silver loving cup was presented to Dr. Elkin as a testimonial of his services to the college, the presentation address being made by Dr. Stewart R. Roberts, Atlanta.——Dr. George L. Loden, Atlanta, has been placed in charge of the Atlanta Municipal Tuberculosis Sanatorium, Battle Hill, vice Dr. Louis Hollander, Atlanta.——Dr. John C. White, Atlanta, has been appointed surgeon of the North Georgia Brigade, United Confederate Veterans.——Dr. Walpole C. Brewer, Atlanta, sailed for Europe on the *Canopic*, May 8, for the Mediterranean. Dr. Brewer expects to join the American Red Cross unit in Vienna.

ILLINOIS

New Hospital.—The new Belvidere Public Hospital, although not formally opened, is in operation. The institution is located in the Warren Rowan homestead. The president of the association is Dr. Alden Alguire, and the secretary, Dr. H. Eugene Delavergne.

Scarlet Fever at Joliet.—Under date of June 18 more than 200 cases of scarlet fever had occurred in Joliet with two deaths. The town was under strict quarantine and the schools with their 14,000 children were idle. Churches, theaters and other public places were closed and travel to and from the city restricted.

Personal.—Dr. Louis F. Morse, Cobden, is said to have suffered a slight cerebral hemorrhage, June 4.——Drs. John L. Taylor, Libertyville, and John C. Foley, Waukegan, with their families, started on an automobile trip to the Pacific Coast, June 15.——Friends of Dr. William J. Uppendahl, Peoria, gave a dinner in his honor at the Creve Coeur Club, June 7, over which Dr. George A. Zeller presided as toastmaster. Dr. Uppendahl sailed for Europe with the Chicago unit for service abroad.

Health Day in the Legislature.—The secretary of the State Board of Health has named June 16 as Health Day in the Illinois Legislature. On this day in addition to giving final passage to the vital statistics bill and the bill restoring jurisdiction over old licentiates practicing medicine or midwifery, two measures which will have an important bearing on the abortion evil in this state, the following were sent to the governor for signature: a bill for prevention of blindness from infections at birth; a bill relating to garbage disposal in small cities. A drainage bill and one relating to creation of small parks on behalf of the State Board of Health.

Chicago

Rush Graduation.—At the annual graduating exercises of Rush Medical College, June 16, a class of seventy-five was graduated and Dr. Edward Carl Rosenow delivered an address on "Recent Advances in Medical Research."

Alienists and Neurologists Will Meet Next Month.—The fourth annual meeting of the Alienists and Neurologists of the United States, under the auspices of the Chicago Medical Society, will be held July 12 to 17. About sixty papers are already on the program and in addition, there will be a half-day clinic at the city psychopathic laboratory on the morning of July 14, and on the next day an all-day meeting at the Chicago State Hospital, Dunning.

Medical Society Election.—At the annual meeting of the Chicago Medical Society, June 15, the following officers were elected: Dr. A. Augustus O'Neill, president-elect; Dr. Charles E. Humiston, secretary (reelected); Drs. Charles H. Miller, Charles C. O'Byrne, Douglas A. Payne, Fred L. Glenn and Jacob C. Krafft, councilors-at-large; and Drs. John J. Toeller, Edward J. Devine, Rachelle S. Yarros, Sadie Bay Adair and Louis H. Friedrich, alternate councilors-at-large.

Meeting of Rush Alumni.—The annual faculty banquet of Rush Medical College, to the graduating class and alumni, was given June 16. Addresses were made by Dr. J. B. Herrick and President Judson of the University of Chicago in which the development of Rush College as a part of the university was forecasted. Prof. L. Hektoen, acting for the faculty, presented a watch to Dr. E. C. Rosenow, who leaves the faculty to become a member of the Mayo foundation. Dr. B. McPherson Linnell has been elected president of the Rush Medical College Alumni Association; Dr. C. A. Parker, secretary; Dr. Elmer E. Kenyon, treasurer.

Upholds Milk Ordinance.—The provision of the milk ordinance, passed Aug. 14, 1912, requiring that milk must be cooled immediately after production and kept at a temperature not exceeding 55 F. from the cow to the dealer in Chicago, has been upheld in the suit of the city against the Northwestern Railroad Company. The railroad resisted the requirement that the milk must be kept cool while in transit on the ground that the city of Chicago had no power to regulate its traffic, but that such powers were reserved to the State Utilities Commission. The municipal court, Judge Trude, held that this department was a valid exercise of the police power of the city concerning an important food product.

Against Quackery in Advertising.—June 21, in the meeting of the Associated Advertising Clubs of the World, the chairman of the vigilance committee following the lead of the president, William Woodhead, recommended that henceforth quackery and fraud in advertising be held to "strict accountability"; and further that the associated clubs engage a salaried force of lawyers, detectives, physicians, chemists and other specialists to put suspicious advertising through relentless tests for the elimination of unsound factors. The recommendations were endorsed by the executive committee and the national commission and then unanimously by the convention. Subscriptions of over $2,000 were made on the floor of the convention for carrying out the purposes of the recommendations, and will be increased during the meeting.

INDIANA

Philanthropic Physician Dies.—News has just been received of the death on June 18 of Dr. Robert W. Long, Indianapolis, whose benefactions to the state have amounted to $245,000.

Advance in Sanitary Welfare.—The cities of Gary, Valparaiso and Indiana Harbor have appointed all-time health officers and Peru will soon follow their example.——Michigan City has recently established a municipal laboratory.

Personal.—Dr. Edwin G. Kyte, Seymour, has been commissioned as first lieutenant, M. C., Ind. N. G.——A banquet and reception was given at Evansville, June 11, for Dr. George W. Buckner, Evansville, United States minister at Iberia.

Sanatorium Site Bought.—The board of commissioners of Marion County has purchased a tract of ground of 25 acres near Oaklandon, about twelve miles from Indianapolis, as a site for a tuberculosis sanatorium. The cost of the land is $9,228.

MAINE

Meeting of Maine State Medical Association.—The sixty-third meeting of the Maine Medical Association was held at Poland Springs, June 9 and 10, under the presidency of Dr. Herman L. Bartlett, Norway. Portland was selected as the next place of meeting and the following officers were elected: president, Dr. Erastus E. Holt, Portland; vice presidents, Drs. Herbert B. Mason, Calais, and Harry A. Snow, Milo; and secretary treasurer, Dr. John B. Thompson, Bangor.

MARYLAND

Patients Transferred.—The Supervisors of City Charities transferred on May 21, one hundred patients from the City Detention Hospital at Bay View, Baltimore, to the Springfield State Hospital, Sykesville, thus reducing the number of patients at the Detention Hospital. Later a large number of negro patients will be transferred to the Crownsville State Hospital.

Clinic Dedicated.—The John Hubner Psychopathic Building and the Springfield State Hospital, Sykesville, was formally dedicated June 9. The speakers included Drs. Henry M. Hurd, Hugh H. Young and Lewellys F. Barker, Baltimore; Edward N. Brush, Towson, and Dr. Elmer E. Southard, director of the Boston Psychopathic Hospital. Mr. Hubner was presented by his fellow members of the board with a gold-lined silver loving cup.

Personal.—Dr. Thomas S. Cullen, Baltimore, who was operated on three weeks ago for gallstones at the Johns Hopkins Hospital has recovered and left for a Canadian island to recuperate fully.——Dr. John S. Davis of Baltimore, who was operated on for appendicitis by Dr. Richard H. Follis, Baltimore, at the Union Protestant Infirmary, has left the hospital.——Dr. William S. Thayer, Baltimore, who was operated on for appendicitis in the Johns Hopkins Hospital, June 4, left the hospital a week later and will recuperate in the north.

MASSACHUSETTS

Medico-Legal Society Meeting.—The annual meeting of the Massachusetts Medico-Legal Medical Society was held in Boston, June 8, and the following officers were elected: president, Dr. Frederick H. Baker, Worcester; vice-president, Dr. Oliver H. Howe, Cohasset; corresponding secretary, Dr. Frederick H. Thompson, Fitchburg; recording secretary, Dr. Harry M. Cutts, Brookline; treasurer, Dr. A. Elliot Paine, Brockton.

New Health Division.—The commissioner of health has established a new department to be known as the Division of Hygiene and has appointed Prof. Selskar M. Gunn of the Massachusetts Institute of Technology, as its chief. Among the duties of this department will be the direction of child welfare work, public health nursing, the promotion of traveling exhibits, the arrangement of public lectures and the distribution of health bulletins and pamphlets.

Personal.—Dr. Samuel H. Hurwitz, Boston, has been appointed instructor in research medicine in the George William Hooper Foundation for Medical Research of the University of California.——Alexander Swanson Begg has been reappointed secretary of the graduate school of medicine of Harvard University.——Dr. Richard C. Cabot has been appointed medical advisor to Radcliffe College.——Dr. George S. Graham has been appointed second assistant pathologist and Dr. Edgar M. Medler research assistant in pathology, at the Boston City Hospital.

State Society Meeting.—The Massachusetts Medical Society held its one hundred and thirty-fourth annual meeting in Boston, June 8 and 9, under the presidency of Dr. Charles F. Withington, Boston. The Shadduck lecture was delivered by Dr. Joel E. Goldthwaite, Boston, on "The Anatomic and Mechanistic Theory of Disease"; the annual discourse was delivered by Dr. Everett A. Bates, Springfield, on "Perplexities in Modern Medicine." The annual dinner and business meeting was held at the Copley-Plaza Hotel on June 9, and the following officers were elected: president, Dr. Charles F. Withington, Boston, (reelected); vice-president, Dr. Edmond F. Cody, New Bedford; secretary, Dr. Walter L. Burrage, Boston, (reelected); treasurer, Dr. Edward M. Buckingham, Boston, (reelected); and librarian, Dr. Edwin H. Brigham, Boston.

Changes in Massachusetts State Board of Insanity.—According to the Bulletin of the State Board of Insanity, the following changes occurred in the board and various state institutions under the supervision of the board in May: Col. Stanhope E. Blunt, Springfield, trustee of the Monson State Hospital, resigned. The following have also resigned: Dr. Arthur C. Zuck from the Taunton State Hospital, and Dr. Ernest J. Clifford from the same institution; Dr. Egbert W. Fell, first assistant physician, from the Psychopathic Hospital, and Dr. Edward T. Gibson as junior assistant from the same institution; Dr. George E. McPherson from the Foxborough State Hospital; Dr. William T. Hanson as medical inspector of the State Board of Insanity, May 20, to accept the position of physician in charge of the mental wards of the State Infirmary. Dr. Dora W. Faxon was appointed second assistant physician at the Foxborough State Hospital.

MONTANA

Banquet to Medical Society.—The annual banquet of the Fergus County Medical Association occurred May 15 at Lewiston. The dominant topic of discussion was "Unity in the Profession."

Personal.—Dr. Clarke S. Smith, Butte, has started for England for war service.——Dr. Robert E. Hathaway, Glendive, had a narrow escape from death by drowning, May 27, when the automobile in which he was driving plunged into a flooded creek.——Dr. William D. Madden has succeeded Dr. Thomas E. Murray as health officer of Great Falls.

Spotted Fever.—A case of Rocky Mountain spotted fever was reported May 15, from Carbon County, in the person of a farm hand who had been bitten by ticks while getting out timber in the mountains of Wyoming.——Another case was that of a real estate man of Great Falls, who was said to have contracted the infection while in Idaho.——The secretary of the State Board of Health announced, May 15, that there had been reported eighteen cases in the state. The disease is being observed in localities other than the Bitter Root Valley, to which the disease has been confined almost entirely in previous years. Ticks are said to be more plentiful this year than ever.

NEBRASKA

Will Organize Field Hospital.—Dr. Herbert H. Smith, Fremont, has organized at Fremont, a field hospital for the National Guard of Nebraska.

Correction.—Dr. Irving S. Cutter, Omaha, secretary of the College of Medicine of the University of Nebraska, advises that the appropriation made by the legislature for the new state hospital building to be erected on the campus of the college, was $150,000 and not $50,000, as stated in The Journal of May 22 and May 29.

Personal.—Dr. James D. Case, Dorchester, has been appointed secretary of the State Board of Health and state health inspector, vice Dr. William H. Wilson, Lincoln.——Dr. Hal C. Smith, Franklin, is reported to be seriously ill in a hospital in Lincoln.——Dr. Arthur C. Bunce, Omaha, who suffered amputation of the leg on account of septicemia, has recovered and resumed practice.

NEW HAMPSHIRE

New Officers.—Manchester Medical Society, June 11: president, Dr. Daniel C. Norton; secretary-treasurer, Dr. Melvin P. Badger.

Personal.—Dr. Charles P. Bancroft, Concord, resumed his position as superintendent of the State Hospital, May 17.——Dr. Daniel F. Wells, Exeter, celebrated his seventy-fifth birthday, May 28.

NEW YORK

Diphtheria in Home for Convalescents.—The Caroline Rest in Hartsdale has an outbreak of diphtheria which drove 100 convalescent mothers and their babies back to New York City.

Personal.—Dr. Elmer H. Ormsby, formerly lecturer in anatomy in Albany Medical College, has opened an office in Amsterdam.——Dr. Edmund C. Boddy, Rochester, sailed from New York, June 18, to take service with the Serbian Red Cross.

Memorial Meeting.—The meeting of the Medical Society of the County of Albany, June 10, was devoted to the payment of tribute to the memory of Drs. Samuel Baldwin Ward and George Gustav Lempe, and the adoption of resolutions regarding the death of these two members.

Joint Society Meeting.—A joint meeting of the medical societies of the counties of Allegany, Genesee, Livingston and Wyoming, will be held at Letchworth Park, Portage Falls, July 15. Papers will be read by Drs. Louis F. Bishop and William S. Bainbridge, New York City. Members of all county societies of western New York are invited to be present.

Field Secretary Appointed.—The National Association for the Study and Prevention of Tuberculosis has appointed Mr. Frederick D. Hopkins field secretary, and he will begin work August 1. He is a graduate of Syracuse University and has had experience in publicity and promotion work. He has recently been employed as an inspector by the New York State Board of Charities.

Interesting Number of Health News.—The May number of the *Monthly Bulletin* of the New York State Department of Health is devoted largely to the subject of the diseases of adult life and the increasing mortality at ages over 45. It is said that the statistics show that while the death rate in the periods of early life is decreasing, the rate after 45 is increasing steadily, due almost wholly to the degenerative diseases of the heart, blood vessels and kidneys. It is found that diseases of the heart at present are exceeded only by tuberculosis as a cause of death, and in one or two years the latter was exceeded by the former. Cancer is also on the increase as a cause of death in adult life. Papers by E. L. Fisk of the Life Extension Institute, and on cancer by Curtis E. Lakeman of the American Society for the Control of Cancer, call attention to these facts and emphasize the required measures of prophylaxis, as is also done editorially in the pamphlet and by graphic charts.

New York City

Hospital Physicians Organize.—The assistant attending physicians of the Willard Parker, Riverside and Kingston Avenue hospitals have organized a society for the study of infectious diseases. The first meeting was held at the Willard Parker Hospital May 4.

Hospital Service for Medical Inspectors.—The Municipal Civil Service Commission has agreed to require as a condition of eligibility for the position of medical inspector in the Department of Health twelve months of hospital experience. An examination for inspectors will be held at an early date.

Dog Muzzling Law Upheld.—The Appellate Division of the Supreme Court in March unanimously sustained the validity of the section of the sanitary code which provides for the muzzling of dogs on any public highway or in any park or place in the city of New York. The test case was known as the Knoblauch case.

Hospital Staff House.—The contract has been let for the erection of the medical staff house and nurses home for the Willard Parker Hospital and the building has been started. The building will be 100 by 83 feet, of concrete fire proof construction and will furnish quarters for thirty-five doctors and 115 nurses, each group being provided a separate entrance, halls, dining room, etc., complete. Swimming pools and gymnasiums will be features of the new building.

Wood Alcohol in Toilet Preparations.—Investigation by the inspectors of the New York City Health Department last year showed that more than one-third of the toilet preparations sold in the city contained wood alcohol, which is forbidden by the Sanitary Code. During the past two months more than 300 preparations taken from barber shops and manicuring establishments and supply houses showed only a small proportion containing this deadly poison. Systematic inspections will be continued.

Personal. — Dr. Benjamin Schwartz has been appointed Coroners' Physician to fill the vacancy caused by the resignation of Dr. Otto H. Schultze.——Dr. William S. Magill returned from Russia June 15.——Dr. William B. Giles sailed June 15 on the *Nieuw Amsterdam* for Falmouth en route for northern France where he is to be surgeon in chief of a British contingent supervised by Dr. Foster Kennedy, New York.——Dr. Frederick Tilney, Brooklyn, has been appointed professor of neurology in the College of Physicians and Surgeons in the city of New York, succeeding Dr. Moses Allen Star, who resigned last month after twenty years of service.——Dr. Ward J. MacNeal has been appointed director of laboratories of the New York Postgraduate Medical School and Hospital, succeeding Dr. Jonathan Wright, resigned.——Dr. Morris Fine has been promoted to adjunct professor of pathologic chemistry; Dr. Richard M. Taylor, to adjunct professor of pathology and Paul A. Schule, to lectureship of bacteriology.

PENNSYLVANIA

Laboratory Installed.—Dr. Francis M. B. Schramm, city bacteriologist of Johnstown, has installed a laboratory on the second floor of the city hall.

Hospital Enlarged.—Plans are well advanced for the enlargement of the capacity of Palmerton Hospital, from fifty to eighty beds. Dr. John W. Luther, surgeon in chief of the institution, is also burgess of Palmerton.

Personal.—Dr. James C. Gray, Cressona, is reported to be seriously ill at his home.—Drs. Louis T. Kennedy and Merchant C. Householder, Pottsville, who have been ill in Chicago, are improving and will soon return home.——Dr. Frederick P. Steck, Shamokin, is taking a trip to the Pacific Coast.

Prize Awarded State Health Department.—A grand prize has been awarded by the International Jury of Awards of the Panama-Pacific Exposition to the Pennsylvania State Department of Health, and Dr. Samuel G. Dixon, commissioner of health, who planned the exhibit, has been given honorable mention.

Philadelphia

Personal.—Dr. S. Lewis Ziegler, director of the Department of Health and Charities, has named Edward A. Lees as assistant director of that department.——Dr. S. Lewis Rubinsohn was operated on at Bushil Sanatorium, June 10.——Dr. William H. E. Wehner has been appointed medical director of the Fidelity Mutual Life Insurance Company, succeeding Dr. William H. King, resigned.

Graduation Exercises.—At the ninetieth annual commencement exercises of Jefferson Medical College, held in the Academy of Music, June 5, the valedictory address was delivered by Dr. Victor Clarence Vaughan of the University of Michigan on the subject, "A Doctor's Ideals."——At the annual meeting of the General Alumni Assocation of the Medico-Chirurgical College of Philadelphia, June 3, the principal address was delivered by Dr. Ernest LaPlace. Dr. William McNeary was elected president and Dr. Charles B. Reynolds, secretary-treasurer.

Fourth of July Precautions.—The safe and sane Fourth committee has planned the distribution of 50,000 pieces of literature to householders and to various schools and institutions, calling on parents and guardians to avoid fireworks. The committee will also have posters placed throughout the city calling attention to the danger attached to the use of explosives. The pamphlet will be illustrated showing a child injured by an explosive and will contain the words, "Will This Happen to Your Child?" Other posters will contain the words, "For Safety's Sake be Sane."

Post-Graduate Teaching Association Organized.—The Cooperative Association for Post-Graduate Teaching of Medicine in Philadelphia has recently been organized by more than 100 practitioners of Philadelphia, with Dr. David Riesman as chairman and Dr. George P. Ruller as temporary secretary. The objects of the association are stated to be to investigate and ascertain the resources for postgraduate teaching that exist in Philadelphia; so to arrange the courses offered by each hospital and college as to enable the students to spend each day in solid study or laboratory work, and the establishment of a central office in charge of the permanent secretary, where rosters of courses may be made and where all information will be listed.

OHIO

Medical Society Revived.—The Preble County Medical Society, which has been quiescent for about two years, has been revived and a meeting was held in Eaton, May 26, to elect new officers and recommence active work.

Health Surveys.—A health survey of Springfield has been commenced by Asst. Surg. L. R. Thompson, and Sanitary Engineer R. E. Tarbett, U. S. P. H. S.——Surg. Carroll Fox, U. S. P. H. S., has completed his health survey of Toledo and returned to Washington.

Room Quarantine Adopted.—After a successful test of the method by Health Officer Daniel W. Iford, Toledo, the city health board has adopted the plan of room quarantine in infectious diseases, and an order has been issued giving detailed quarantine instructions under this method of handling infections. This places the afflicted person in charge of a nurse or other member of the family who must be completely isolated from the other members. The latter are allowed to pursue their usual occupations.

Philadelphians Address Academies.—On May 21, Dr. Richard M. Pearce, Jr., professor of research medicine in the University of Pennsylvania, delivered an address before the Academy of Medicine of Cleveland, on "The Relation of the Spleen to Blood Destruction and Regeneration and to Hemolytic Jaundice." After the lecture a smoker was given at the University Club by the heads of the department of medical research and of the various laboratories of the School of Medicine of Western Reserve University.——Dr. John A. Kolmer, director of the Research Laboratory of Pathology of the University of Pennsylvania, was the guest of the Academy of Medicine of Toledo and Lucas County, May 14, and delivered an address on "The Mechanism and Diagnostic Value of Anaphylactic Skin Reaction."

Personal.—Dr. Thomas G. Farr, the oldest practitioner of South Charleston, was the guest of honor at a banquet before the Clark County Medical Society in Springfield, June 9. After the dinner Dr. Farr was presented by the Society with a leather covered easy chair.——Dr. Harry E. Welch, Youngstown, was elected a vice president, and Dr. Louis H. Frechtling, Hamilton, a trustee of the Ohio Society for the Prevention of Tuberculosis at its meeting in Columbus, June 7.——Dr. Chelsea A. Coleman, Dayton, has filed suit in the common pleas court for $5,000 damages on account of injuries to his legs and damages to his automobile, said to have been suffered May 4, last.——Dr. James H. Lowe, Piqua, has been elected president of the Miami Valley Health Officers Association.——Dr. Louis L. Syman, Springfield, who was operated on for appendicitis at the Springfield City Hospital, June 3, is reported to be doing well.——Dr. Reginald L. Cameron, Cleveland, has been appointed chief surgeon of the Republic Rubber Company and also placed in charge of the welfare department.——Drs. Lucian G. Locke and Charles W. Wendelken, Portsmouth, have been elected trustees of the Antituberculosis Society of Scioto County.

Cincinnati

Portrait Presented.—A portrait of Dr. Joseph Aub, prominent as an eye, ear, nose and throat specialist of Cincinnati, who died in 1888, was hung in the reception room of the

Cincinnati General Hospital, May 28. The painting was presented by the widow of the physician.

New Home for Academy.—Plans for the erection of a new home for the Cincinnati Academy of Medicine to cost $250,000 were discussed at a meeting, June 7. A building committee of five was appointed and it is planned to erect a building on Seventh, Eighth or Ninth streets with one floor for stores, the second, third and fourth floors for offices of physicians and dentists and the upper floors for meeting rooms, library, lecture rooms and laboratories for the Academy of Medicine.

Personal.—Dr. John H. Perry, assistant superintendent of Longview Hospital, has resigned his position to accept a similar post at the Hospital for Criminal Insane at Lima, Ohio.——Dr. Horace F. Tangeman has been appointed otolaryngologist to the Branch Tuberculosis Hospital.——Dr. John A. Caldwell, Jr., has been appointed junior surgeon and Dr. Edgar C. Steinharter, junior gynecologist to the Cincinnati Hospital.——Dr. Albert H. Freiberg has had conferred on him the honorary degree of LL.D. by Cedarville College, Cedarville, Ohio, on account of his distinguished services to humanity in the field of orthopedic surgery.

Emery Gift to the University.—Mrs. Mary M. Emery has made a provisional gift of $250,000 for the construction of a new building for the Ohio-Miami Medical College of the University of Cincinnati, conditional on the raising of a like sum to equip the new building. Mrs. Emery's munificent gift is in gratitude to the profession of medicine and with a desire to further its powers of alleviating the ills of humanity. The new building will be located immediately adjoining the new Cincinnati General Hospital on the north and close to the pathologic building of that institution. The new medical school will consist of a central four-story building and two three-story wings conforming in general architectural plan to the Cincinnati General Hospital. Active work is commenced on the raising of the additional $250,000, on the securing of which, Mrs. Emery's offer becomes available. Mr. Harry M. Levy has already given $50,000 toward this fund.

OKLAHOMA

Health Department Moved to Guthrie.—Permission having been granted by the governor, Dr. John W. Duke, Guthrie, state health commissioner, has moved the office of the State Health Department to Guthrie.

New State Board of Medical Examiners.—Governor Williams has appointed the following board of medical examiners: Dr. Ralph V. Smith, Tulsa, secretary; and Drs. Le Roy Long, McAlester; B. L. Denison, Garvin; Ernest B. Dunlap, Lawton; William T. Ray, Gould; Melvin Gray, Mountain View; and William L. Bonnell, Chickasha.

State Association Election.—At the annual meeting of the Oklahoma State Medical Association held in Bartlesville, May 11 to 13, under the presidency of Dr. John W. Riley, Oklahoma City, the following officers were elected: president, Dr. J. Hutchings White, Muskogee; vice presidents, Drs. Walter Penquite, Chickasha; John P. Sudderth, Nowata, and W. Albert Cook, Tulsa; and delegate to the American Medical Association, Dr. John W. Riley, Oklahoma City. Oklahoma City was selected as the next place of meeting.

Personal.—Dr. David A. Myers, Lawton, is recovering from injuries received when his automobile ran over him while he was cranking it when in gear.——Dr. Henry Cone, Maud, was acquitted on the plea of self-defense at his trial recently for shooting and killing a tenant on his farm. ——Dr. Leander M. Overton, Fitzhugh, was struck by an automobile and sustained a fracture of the skull, clavicle and a Colles fracture.——Dr. Clarence C. Shaw, Tishomingo, has been appointed state prison physician, succeeding Dr. John W. Echols, McAlester.——Dr. Joel R. Holliday, Oklahoma, has been appointed a member of the Board on Sanity, succeeding Dr. Ross D. Long, Oklahoma, who has been given an indefinite leave of absence by county commissioners, and has sailed for Europe.

OREGON

Personal.—Dr. Richard A. Nunn, Portland, sailed for Europe, May 8, and expects to be placed on duty in one of the English hospitals.——Dr. Charles J. Smith, Portland, was elected chairman of the State Board of Higher Curricula at its meeting for organization.——Dr. Shelly Saurman, director of the bacteriologic laboratory of the State Board of Health, has resigned and will locate in Burns.

College Adopts Higher Requirements.—The announcement of the University of Oregon, department of medicine, just received states that after Jan. 1, 1916, two years of collegiate work, including courses in physics, chemistry, biology and French or German, will be required for admission. There are now forty-three colleges and nine state licensing boards which have adopted this higher requirement.

Physicians Win Suit.—The suit brought by Iris W. T. Oliver against Drs. James P. and Brice R. Wallace, Albany, for alleged malpractice in setting a fracture of the shoulder, in which $25,000 damages were asked, was decided May 4, in favor of the physicians. The testimony showed that the treatment of the case was thoroughly scientific and in accordance with the latest and most approved method.

VIRGINIA

Hospital Notes.—The committee on plans for the new Alexandria Hospital has made a contract with an architect of Washington, for the preparation of plans for the building. ——Clergymen of Norfolk have united in a campaign to raise $25,000 to make up the deficit of the Protestant Hospital, Norfolk.

Health Association Meeting.—At the annual meeting of the Virginia Public Health Association, held in Lexington, May 10, to 12, the following officers were elected: president, Dr. John W. H. Pollard, of Washington and Lee University, Lexington; vice presidents, Drs. C. Curtis Hudson, Danville, and Thomas J. Pretlow, Newport News; secretary-treasurer, Dr. W. B. Brownley Foster, Roanoke, and assistant secretary-treasurer, Dr. Roy K. Flannagan, Richmond.

Alumni Election.—At the annual meeting of the Alumni Association of the Medical College of Virginia, Richmond, June 1, the following officers were elected: president, Dr. Lewis C. Bosher, Richmond; vice presidents, Drs. Achilles L. Tynes, Staunton; Thomas S. Hening, Jefferson; William K. McCoy, Gum Spring, and Richard C. Waldon; secretary, Nathaniel T. Ennett, Richmond; assistant secretary, Dr. James H. Smith, Richmond, and treasurer, Dr. Frank H. Beadles, Richmond.

Personal.—Dr. Allen W. Freeman, Richmond, assistant state health commissioner, has resigned to become epidemiologist in the United States Public Health Service.——Dr. Ennion G. Williams, state health commissioner of Richmond, was elected president of the Conference of State and Provincial Boards of Health of North America, at its meeting in Washington, recently.——Dr. William L. Dunn, Abingdon, has been elected surgeon of the William Jones Camp, United Confederate Veterans.——Dr. Harry T. Marshall, Charlottesville, of the University of Virginia, has been appointed a member of the state tuberculosis commission. This commission is to serve without pay and is to consider the question of tuberculosis in all its phases and to report to the next general assembly a comprehensive plan for the control of the disease.

WISCONSIN

Physicians' Building in Green Bay.—Contracts have been awarded for the construction of the Bellin-Buchanan Building, Green Bay. The contract calls for a building 66 by 105 feet and six stories in height, which is to be devoted especially to the use of physicians and dentists.

Hospital Notes.—Dr. Christian U. Senn, Ripon, has associated with him Dr. U. Senn, Milwaukee, and will establish a hospital in the near future. The building at the corner of Ransom and Blossom streets is to be remodeled for this purpose.——A permit has been issued for the construction of an addition to the Milwaukee Hospital for Contagious Diseases, which is to be erected at a cost of $90,000.

Sanatorium Notes.—Ground for a new tuberculosis sanatorium for Kenosha County was broken, May 19, and it is hoped that the construction of the building will be carried on without delay.——The trustees of the Milwaukee County Tuberculosis Sanatorium have asked the people of Milwaukee to suggest a name for the new institution. Suggestions are to be sent to Dr. Hoyt E. Dearholt, Milwaukee.

Personal.—Dr. Urban J. Durner, Milwaukee, has received an appointment as house surgeon in the Eye, Ear, Nose and Throat Infirmary of Middlesex Hospital, London.——Dr. Gustav Windersheim has been reappointed chairman of the Board of Health of Kenosha.——Dr. Frank I. Drake, head physician at the State Prison, Waupun, has succeeded Dr.

Charles Gorst, as superintendent of the Mendota State Hospital.——Dr. Norman Hoffman has been reappointed superintendent of the State Open Air Sanatorium for Tuberculosis, Wales.——Dr. Alfonse F. Kalkhoff, Milwaukee, fell on a sidewalk, recently, fracturing his left arm.——Dr. Gustavus I. Hogue, Milwaukee, has been elected president of the Northwestern Alumni Association of the Southwestern District of Wisconsin.

WYOMING

Personal.—Dr. Henry W. Greist, Casper, is suffering from complete paralysis of the left facial nerve, probably due to exposure.

Tick Fever.—Five fatal cases of Rocky Mountain spotted fever have occurred in Montana this year, to June 4, and there has been a great increase in the number of cases. Ticks are unusually plentiful on account, it is believed, of the extraordinary amount of rain throughout the spring months.

New Quarantine Order.—A new quarantine order, superseding that of April 1, has been issued by the governor. By this order it is permitted to ship into Wyoming, cattle, hogs, sheep and horses from the states of Washington, Oregon, California, Idaho, Nevada, Arizona, Utah, Montana, Colorado, New Mexico and Texas, if accompanied by a health certificate, and from North Dakota, South Dakota, Nebraska, Kansas, Oklahoma, Louisiana, Arkansas, Missouri, Iowa and western Minnesota, on special permit issued by the state veterinarian.

CANADA

Anatomy Professorship Endowed.—Dalhousie University, Halifax, N. S., has received a gift of $30,000 toward the endowment of a chair of anatomy. An announcement is made that this sum will be doubled in the near future.

Sanitary Corps Organized.—Dr. Thomas A. Starkey, Montreal, has organized a sanitary corps for overseas service, of which he will be in command. It will be composed of students of McGill University and will number twenty-eight men. They expect to leave for England shortly.

Ambulance Donated.—The telephone girls of Toronto have presented a motor ambulance valued at $1,800, fully equipped and ready for service to the Canadian Red Cross Society. ——The Hon. Charles Dalton of Charlottetown, P. E. I., has offered to provide a motor ambulance for Red Cross work at the front.

More Surgeons Needed.—The British War Office is asking for more doctors. Candidates must be British subjects, under 40 years of age and graduates of some Canadian medical college. They must pass the regular military service examinations, be members of the Army Medical Corps and vouched for by the authorities of that corps.

Ontario's Offer Accepted.—The War Office has accepted the offer of the Ontario Government to provide a hospital of 1,040 beds in England for wounded soldiers. There have been many applications for positions on this hospital. The following names have been mentioned as likely to receive commissions: Drs. Rowland B. Orr, Herbert A. Bruce, Herbert J. Hamilton and Harry B. Anderson, all of Toronto.

Personal.—Dr. Thomas P. Bradley, Sarnia, Ont., has volunteered for special service overseas with the Royal Army Medical Corps.——Drs. F. W. Manning and Charles R. Totton, Windsor, have been accepted by the Canadian Government for service with the Army Medical Corps in France.——Dr. Irving Heward Cameron, professor of surgery in the University of Toronto, has left for England to accept the position of honorary visiting surgeon on the staff of King George Hospital, an institution with 1,600 beds, recently founded. Professor Cameron will be associated with Sir Frederick Treves, Sir Arbuthnot Lane and other distinguished English surgeons.——Dr. Michel Lefevre, Maisonneuve, Que., has left on an extended trip to California.——Dr. E. Vincent Sullivan, St. Stephen, N. B., has left for Montreal to sail at an early date with the Army Medical Corps for Europe.——Dr. Harris C. Mersereau, Montreal, is going to the front in command of a field ambulance.——Dr. Alfred B. Atherton, Fredericton, N. B., has returned from an extensive trip to California.——Dr. Lorne D. MacIntosh, Hartland, N. B., has sailed for England to act as surgeon in the Imperial Army Medical Corps.——The Hon. Dr. Henri S. Beland, St. Joseph, Que., one time member of the Laurier Government in Canada, has been interned from Belgium where he was when the war broke out. He is now in Germany as a prisoner of war. Dr. Beland had been attending wounded Belgian soldiers in the castle of Capellan.——Dr. James E. M. Carnwarth, Riverside, Hopewell Hill, N. B., had an unusual experience on a recent professional trip returning from a night visit. His motor car ran into two moose lying on the road.——Dr. Harry B. Lawson, Rolling Dam Station, N. B., has departed for Montreal to sail for the war.——Dr. Alan H. N. Kennedy, Macleod, Alta., has been appointed medical referee for the province of Alberta under the Workmen's Compensation Act.

GENERAL

Red Cross Seals.—The American National Red Cross has placed an order for 125,000,000 Red Cross seals for 1915. New regulations in regard to procuring and selling these seals will soon be published in the Bulletin of the Red Cross.

American Surgeons Meet in Minnesota.—At the annual meeting of the American Surgical Association held in Rochester, Minn., June 9 to 11, the following officers were elected: president, Dr. Robert G. LeConte, Philadelphia; vice presidents, Drs. Charles L. Gibson, New York City, and Archibald MacLaren, St. Paul; secretary, Dr. John H. Gibbon, Philadelphia; recorder, Dr. John F. Binnie, Kansas City, Mo.; and treasurer, Dr. Charles H. Peck, New York City. The 1916 meeting will be held in Washington.

Throat, Nose and Ear Specialists Hold Meeting.—At the twenty-first annual meeting of the American Laryngological, Rhinological and Otological Society, held in Chicago, June 16, the following officers were elected: president, Dr. Seth MacCuen Smith, Philadelphia; vice presidents, Drs. William B. Chamberlain, Cleveland; John B. Rae, New York City; Robert C. Lynch, New Orleans, and Thomas E. Carmody, Denver; secretary, Dr. Thomas J. Harris, New York; and treasurer, Dr. Ewing W. Day, Pittsburgh. The gold medal of the society offered for research work was awarded to Dr. G. H. Cox, New York City.

Congress Postponed.—Dr. J. Riddle Goffe, New York City, president of the Seventh International Congress of Obstetrics and Gynecology, announces that the meeting scheduled for September of this year will be postponed until September, 1917. This decision was reached at a meeting of the American Executive Council of the Congress recently held in St. Louis. It was decided that the expenses thus far incurred to the congress should be deducted from the subscriptions of the members of the American Executive Council of America and that the subscriptions of all other members of the organization committee should be returned to them until money is again needed in the preparation for the congress.

New Regulation Under the Harrison Narcotic Law.—The following bulletin has just been issued by the Commissioner of Internal Revenue, interpreting Regulations No. 35, Supplement No. 2, of the Harrison Narcotic Law, requiring a separate application for registry and payment of special tax if the applicant has more than one place of business, with no exception.

> Art. 1. The second paragraph of this article is hereby amended, effective on and after this date, to read as follows:
>
> If the applicant has more than one place of business, or if, in any case, the applicant is engaged in more than one profession or business where any of the drugs above described are made, stored, or dispensed, a separate application for registry must be made, and a special tax must be paid, in each such case.

Bequests and Donations.—The following bequests and donations have recently been announced:

For the establishment of a hospital in Bluffton, Ind., $1,000, by the will of Herman Wicking, Ridgewood, N. J.

Chicago Lying-In Hospital, $100,000, from Mrs. Julius Rosenthal.

Maine General Hospital and Maine Eye and Ear Infirmary, Portland, each $50,000, contingent bequests by the will of John E. Martin.

St. Louis Skin and Cancer Hospital, the income of the estate of George D. Barnard, appraised at $2,000,000.

Montefiori Home and Mount Sinai Hospital, New York City, each $10,000; United Hebrew Charities, Guild for Crippled Children and New York Skin and Cancer Hospital, each $2,500, by the will of Mrs. Amelia Lavenburg.

St. John's Hospital, Brooklyn, N. Y., $2,000, by the will of Mrs. Julia E. Beals.

Episcopal Hospital, Philadelphia, $5,000, for the endowment of a free bed to be known as the William H. Richardson free bed, by the will of Alice H. Richardson.

St. Joseph's Hospital, Philadelphia, $5,000, for the endowment of a free bed in memory of the late Rear Admiral Jackson McElmell, U. S. N.; St. Agnes' Hospital, Philadelphia, $5,000, to endow a free bed in the name of the testator by the will of Thomas A. McElmell.

West Philadelphia Hospital for Women, donations of $5,000 each, from Miss Mary Burnham and Miss Elizabeth Shippens, and $1,000 by the will of Mrs. Theodore Lewis, all to be devoted to the Maternity Building fund.

Presbyterian Hospital, New York City, $30,000, by the will of Mrs. Evelina A. Meserole.

Red Cross Work in Mexico.—Two carloads of food sent by the American Red Cross to Monterey, Mexico, have been received and greatly appreciated by the starving people. More than 20,000 have already been fed.——Corn for 7,000 was supplied at the American Hospital at Monterey, on June 5.——Corn, beans and rice are the most urgent needs.——General C. A. Duval, general manager of the American Red Cross, has been conferring with Major-General Frederick Funston, regarding the direction of the Mexican relief campaign. He also visited the various border points to expedite and safeguard the handling of relief stores.——Consular agents throughout Mexico will cooperate with the Red Cross and the military authorities on the border in the forwarding of supplies.——Two additional cars of corn have been sent to Monterey.——The American Red Cross shipped on June 10, twenty-five cases of drugs and hospital supplies to the United States consul at Vera Cruz, to be forwarded to the Spanish, American and French hospitals in Mexico City.——Famine conditions are said to prevail at Vera Cruz and in the surrounding country.——At Jalapa conditions are said to be appalling. More than 2,500 women stood in line for the distribution of rations.——Acapulco, on the west coast, is practically without food supplies and the inhabitants are reported to be starving.——Shortage in all cereals is reported all over Mexico and in Mexico City, thousands are said to be in danger of perishing from hunger and epidemic diseases.——Smallpox and typhus fever are reported to prevail in the city of Mexico.

The Campaign Against Cancer.—The American Society for the Control of Cancer urges every state medical society to take an active part in arranging meetings for the spread of the latest knowledge among members and the public of malignant disease. The Pennsylvania State Medical Society has suggested that medical journals help in the propaganda and many of them will devote their July issues to the cancer problem. The American Society has recently restated its relation to the cancer campaign and to the various other organizations working along the same line. The national society has endeavored to work in harmony with other agencies and so to arrange its work and organization as not to duplicate efforts in cancer prevention. It organizes no local societies where existing agencies cover the field, and will not attempt to enter the field of biologic research already so well covered under the auspices of the leading universities. The society expects, however, to expand that feature of its work relating to the collection and collation of statistical data, which need to be improved both as regards their collection and publication. At the suggestion of the society the United States Census Bureau immediately began the preparation of a report on the cancer mortality in the United States registration area in 1914. In this report the deaths will be stated in detail under some thirty titles of organs and parts of the body affected, rather than, as hitherto, under the six general groups of the international list. This will conform to the plan of the Imperial Cancer Research Fund, making the data available in the same form as those of England and Wales. The bureau will also attempt to make a distinction between returns based on certain and on doubtful diagnoses, and to establish this is making inquiry of physicians reporting cancer cases as to whether the diagnosis was based on clinical findings alone or was established by surgical operation, microscopic examination or necropsy. Much of this work, it is believed, should be done in the first instance by registration officers or the boards of health of the various states where the original certificates of death are filed. The society urges on the various state officials the need of doing this work in order to insure the permanence of the improvement in the statistical study of cancer which has been inaugurated by the census bureau. The society is further interested in and will give special attention to special statistical studies of the geographic, racial and occupational distribution of cancer, and endeavor to collate on a uniform plan the records of the surgical treatment of the disease in the leading hospitals so that an authoritative answer may be available to inquiries as to what percentage of success is to be expected in the treatment of cancer in each of its phases and stages.

WAR NOTES

Swedish Hospital at Paris.—The Swedish colony in Paris has established a hospital within the premises of the Swedish church in the rue Guyot. The *British Medical Journal* states that the hospital makes a specialty of Swedish massage by experts. Dr. Périer is in charge of the hospital.

Typhus Conquered in Serbia.—Advices to the *British Medical Journal* of June 5 confirm the news that the epidemic of typhus in Serbia is now virtually extinct. On April 5, there were 8,198 cases of typhus at Nish and by April 18, only 948. The number of cases of relapsing fever had dropped from 7,693 to 4,861.

Philadelphia Unit Leaves for War.—The University of Pennsylvania expedition composed of doctors and nurses led by Dr. J. William White, sailed from New York, June 12, on the *St. Louis* for work in the American Ambulance, Paris. The medical members of the party are Drs. James P. Hutchinson, chief surgeon; Daniel J. McCarthy, neurologist; Drs. Edmund B. Piper, Arthur E. Billings and Peter M. Keating, assistant surgeons; Dr. Samuel Goldschmidt, bacteriologist; Drs. Thomas Galler and D. M. Davis, assistants, and four nurses.

Armenian Red Cross Fund—Armenia joins Russia in the eastern part of Asia Minor, and 10,000 Armenian volunteers are now fighting in the Russian army. This number will soon be doubled, but they have no medical men except a few medical students from Kieff. Armenians all over the world have equipped and maintain the soldiers, but there are no Red Cross appliances of any kind. Thousands of refugees have crossed the border into Turkestan, 12,000 are known to be at one point. An appeal for a Red Cross and Refugee fund for the Armenians is published in the *Lancet*; the treasurer is Mr. H. A. Godson Bohn, 17 Holland Villas Road, Kensington, England.

New Motion Picture on Tuberculosis.—It is announced in the Bulletin of the National Association for the Study and Prevention of Tuberculosis that after several months of work the association, in cooperation with the Universal Film Co., has produced a new four-reel film called the "White Terror." It is said to be a production with "dramatic punch," carrying several lessons concerning the use of fake cures for consumption, the danger of bad housing and working conditions and the evils of political corruption as it relates to public health. As this film will be distributed in the regular service of the film company, which supplies half the theaters in the United States, it will be seen by a large number of persons.

The Touring Club and the War.—The efforts in recent years of the organized automobilists of western Europe to improve the roads have proved of signal service in the military operations in the last few months. The headquarters of the Touring Club of France are in the magnificent premises where was kept the safe supposed to contain the fabulous fortune of the Humberts. The members of the club are mostly fighting at the front, and the building has been devoted to the preparation of packets of gifts to be sent to the men on the firing line. Souvenir postcards, medals and little flags were sold to add to the funds for this purpose, all commemorating the big gun, "the seventy-fiver." They were sold by the thousands of members of the Touring Club for a few pennies each, and the *Lancet* states that special arrangements had to be made with the banks to deal with the huge amounts of small coins thus turned into the treasury of the club. Far over a million dollars had been realized by the first of June, and the reports are not all in.

Aid for Belgian Physicians.—The report of the treasurer of the committee of American physicians for the aid of the Belgian profession, for the week ending June 19, 1915, lists the following contributions:

Dr. L. O. Tarleton, 1st Lieut. U. S. A., Manila, P. I.		$ 5.00
Norwich Medical Association, Norwich, Conn.		25.00
Westmoreland County Medical Society, Mount Pleasant, Pa.		25.00
Elmira Academy of Medicine, Elmira, N. Y.		50.00
Dr. Angus McLean, Detroit, Mich.		30.00
Receipts for the week ending June 19		$ 135.00
Previously reported receipts		7,312.00
Total receipts		$7,447.00
Previously reported disbursements:		
1,625 standard boxes of food at $2.20	$3,575.00	
1,274 standard boxes of food at 2.30	2,930.20	
353 standard boxes of food at 2.28	804.84	
Total disbursements		7,310.04
Balance		$ 136.96

F. F. Simpson, M.D., Treasurer,
5 Jenkins Arcade Bldg., Pittsburgh, Pa.

Repair after Wounds of the Jaws.—The *Lancet* reproduces an account of a visit to the Strassburg hospital where a staff of specialists is striving to reduce to the minimum the ravages caused by wounds of the mouth and face. It is said to be the first that has ever been organized in any war for the treatment of wounds of the face and jaw. "The staff numbers fifty-five, and all the work (including the cooking), which is done by the wives and daughters of the professors, is performed without fee. The hospital itself is divided into two sections. In the first a dozen dentists examine the teeth of the soldiers, extract, and make plates. This work is carried out at the cost of the military authorities, who adopt the very reasonable point of view that a soldier with defective teeth cannot be thoroughly efficient. The remaining section of the hospital itself comprises two subdivisions—the operating theater and the department in which are made the prosthetic molds destined to replace the bones or sections of bone sacrificed in the operation, and the surgical work is entirely done by dentists, most of whom have taken their medical degree. The wounded are photographed and roentgenographed on their arrival and photographed before departure, and these photographs and roentgenograms will constitute a collection of the highest scientific interest." At the moment of the visit more than 200 soldiers were undergoing treatment there, and the results already obtained are said to be almost marvelous.

BERLIN LETTER

Berlin, May 26, 1915.

Visit to Camp of Prisoners of War

A party of 400 Berlin physicians, May 25, visited the camp of war prisoners installed near Berlin on the large parade ground at Döberitz. About 9,500 prisoners are quartered there, housed in new wooden barracks, partitioned off. The camp is laid out in blocks, and the prisoners are quartered by nationalities.

Although the requirements as to food differ according to the nationality, the profession and other individual peculiarities, yet nowhere were visible signs of insufficient nourishment. Not a few of the captives appeared excellently well nourished. As is easily understood, the living rooms and especially the sleeping quarters are primitive. The governments now have to care for 1,400,000 prisoners in the various concentration camps. The prisoners keep in the open air almost all day long, and the open windows and doors provide for ample ventilation. Everywhere we found good air in the barracks.

All the prisoners are obliged to keep themselves clean. Each one is compelled to take a shower-bath every day, a simple but well-working shower-bath arrangement being installed in each barracks. Every three weeks the clothing of each of the prisoners is sterilized with hot air. There is a huge central establishment for washing the body linen, and in each block there is a separate wash-house where the captives can clean their clothes and linen.

Each captive receives daily 300 gm. of bread, with coffee, tea or soup in the morning; at noon, one-fourth liter soup, with vegetables, potatoes and 100 gm. meat; for supper, soup, with sometimes tea or chocolate. There is a cook-room in each block, where the meals are prepared in four large kettles. Near the cook-room there is a bar or canteen where articles of food and clothing and sewing materials are for sale at fixed, very low prices. Most of the captives are able to supplement the regular ration served out to them as they receive donations forwarded to them from their homes. A special pavilion is devoted to this package service, eight officials receiving and carefully examining the parcels and handing them over to the prisoners.

There are four latrines to each block. The cement floors of the closets are flushed with a perpetual flow of water sweeping the excreta at once into the sewer, so that there are no disagreeable odors in or around the latrines.

ARRANGEMENTS FOR THE SICK

Three pavilions in the camp shelter the sick, one for internal medicine, one for surgery and one for contagious diseases. Besides these there is an isolation pavilion, fifteen minutes' walk from the camp. The health of the Döberitz camp is very good; there were only nine inmates in the medical ward and ten in the surgical, none very sick, and the contagious pavilion was empty. In the isolation pavilion there were a few tuberculous French prisoners. Two Russian and two English army surgeons have charge of the sanitary and hygienic care of the prisoners.

HOW THE PRISONERS PASS THE TIME

At present there are only 3,500 captives in the camp, as 6,000 are being utilized in farm work in the neighborhood. The captives still in camp are also occupied in farm or road work or called on for service inside the camp. In special cases more freedom is allowed, as, for instance, in one small building where several artists are at work, painting portraits and other pictures, paints having been supplied them by gifts from friends at home. A large tent has been set up for a Russian theater, the stage setting artistically adorned by some of the Russian prisoners. There is a similar institution also for the English, and we had the peculiar pleasure of hearing an orchestra of English prisoners render the overture to Don Giovanni. The orchestra is only partly composed of professional musicians.

PARIS LETTER

Paris, June 3, 1915.

The War

A NEW IMPROVEMENT IN THE TRANSPORTATION OF THE WOUNDED

The transportation of the wounded, which was the weakest side of the organization of the medical service at the beginning of the war, has since then been considerably improved. The removal of the wounded has been so far accelerated that at noon, April 29, soldiers who had been wounded at the Yser on the 28th were received at the station of La Chapelle, which is the distributing point for the entrenched camp of Paris. This progress is due in part to the greater number of medical service trains. There are at present more than 200 of these. It is also partly due to a change in method. For many months wounded men were transported like ordinary passengers, being fed and their wound dressed at the station infirmaries. Now there are three kinds of medical service trains: (1) trains called permanent, which are composed of special coaches for the exclusive use of the wounded; (2) trains called semipermanent, which are composed either of baggage cars arranged for reclining wounded men or of passenger cars with a side aisle (these coaches are arranged to receive both seated and reclining wounded men); (3) trains called improvised, made up of coaches or of baggage cars fitted up with apparatus for suspending litters and intended to receive wounded men who are unable to sit up (these last trains are utilized only for intensive evacuations).

To make of each train the hospital on wheels demanded by the medical service, however, certain indispensable features must be provided. The departmental instructions prescribe only the addition to the train of a restaurant car, which is to serve as an office, a pharmacy, a dressing room, a diet kitchen and a dining room for the staff. This solution, which answered as a makeshift during a period of transition, is really unsatisfactory. It is impossible to adapt to such various uses a single restaurant car. Moreover, each one of these cars weighs 37 tons. To carry one of them three coaches of wounded men must be omitted. Something better, therefore, is required. Commandant Carcenat, commissary officer of one of our stations, has endeavored to solve the problem. He has devised the transformation of an ordinary baggage car 9.5 or 10 meters (31 or 33 feet) long into either a dining car or a hospital car. The dining car comprises the kitchen, with stove, coffee urn, cupboard and pantry, and a dining room for sixteen men. The cost of fitting it up is about 800 francs ($160). The hospital car comprises three rooms: (1) a diet kitchen with a very small water heater surrounded by asbestos, capable of boiling 200 liters of water in an hour (this permits the preparation of hot drinks and of aseptic dressings at any hour of the day or night); (2) the pharmacy, containing indispensable remedies such as morphin and caffein, ampules of cocain and ether and antitetanic and antidiphtheric serums; (3) a very simple dressing room, but arranged according to all hygienic rules with an operating table composed of two tripods connected by a cross bar on which the litter is placed. Every soiled object is thrown into the furnace of the locomotive at the first stop. The cost of fitting up a baggage car as a hospital is about 1,100 francs ($220).

To increase the number of these moving hospitals as much as is desirable outside assistance is permitted. The city of Paris has just fitted up, at its own expense, seven baggage cars as kitchen and dining cars. The city of Lyons has done the same. Societies and private persons can easily collect the amount necessary for such refittings.

RESULTS OBTAINED AT THE SCHOOL FOR CRIPPLES AT LYONS

I mentioned in my previous letters (The Journal, March 13, 1915, p. 923, and May 15, 1915, p. 1671) various endeavors which have been made to reeducate cripples for vocations. M. Edouard Herriot, mayor of the city of Lyons and senator of the department of the Rhone, has just reported the results already obtained in the first Ecole professionelle de blessés at Lyons. The school has at present ninety-three pupils, eighty-five resident and eight nonresident. It gives instruction in the following subjects: (1) bookkeeping, stenography, typewriting, etc.; (2) shoemaking; (3) sewing; (4) carpentry and joinery, and (5) bookbinding. It is also proposed to lay out extensive grounds for the instruction of some of the war cripples in horticulture.

All the pupils employed in manual labor are obliged to give their evenings to courses of general instruction graded according to the previous education of the pupils.

The purpose of the school is to produce not merely passable workmen but model workmen, and to combat the tendency of crippled soldiers to seek for wretched little government jobs. In order to keep the pensioners as long as may be necessary to teach them the complete technic of their trade and permit them to become teachers, employers or foremen, they are given substantial inducements; that is, they are given free board, no claim being made on the allowance made them by the government, and at the same time they are permitted to receive the returns from their daily work.

IMMEDIATE TREATMENT OF WOUNDS OF WAR BY CONCENTRATED SOLUTIONS OF SEA SALT

At a recent session of the Société de chirurgie de Paris, Dr. Abadie of Oran reported good results obtained by treating wounds with concentrated solutions of sea salt which, being hypertonic, produced an exosmosis, thus bathing the tissues while promoting diapedesis. These solutions, unlike antiseptics, are not toxic for the cellular elements. After the wounds have been freely laid open and carefully cleansed, removing the dead and suspected tissues, Abadie irrigates freely with a 0.7 per cent. solution of sea salt and then packs the wound with gauze wet in the mother solution of from 14 to 28 per cent. A thick dressing is necessary because of the abundant serous effusion. This mode of treatment gives red and healthy wounds, in which infections are aborted at the start. Old wounds are deodorized and the general condition is not comparable to that ordinarily presented by severe wounds.

Dr. Morestin, surgeon of the hospitals of Paris and agrégé, has also made much use of salt but not in precisely the same conditions as those reported by Abadie. He has used it especially in the treatment of old wounds and particularly of varicose ulcers. The salt rapidly modifies wounds which are atonic or covered with exuberant granulated tissue. It gives them a healthy appearance and hastens repair. This treatment, however, has the disadvantage of being painful.

THE DANGER OF PUTTING TYPHOID AND PARATYPHOID PATIENTS IN THE SAME WARD

At a recent session of the Société médicale des hôpitaux de Paris, Drs. Jeanselme and E. Agasse-Lafont reported a case of successive infection first by the paratyphoid B bacillus and then by the Eberth bacillus, which raises an important problem of prophylaxis. A soldier brought back from the front who had been infected with paratyphoid B was placed in an isolation ward in which there were both typhoid and paratyphoid patients. The case first ran a normal course and then seemed to have a relapse, which was followed by a second relapse. The possibility was then considered of the complication being not a relapse but a new infection. Serodiagnosis with the Eberth bacillus, which had been negative during the first attack, was now found distinctly positive.

This fact seems to indicate that typhoid and paratyphoid patients should be separated, the two groups of patients being dangerous to each other, since the two diseases are absolutely distinct and neither immunizes against the other, as has been proved by vaccination. Prudence is all the more desirable since cases of paratyphoid are now extremely frequent, being even more numerous in certain regions than cases of true typhoïd.

AN AMERICAN FIELD HOSPITAL

A field hospital of the type used in the American army has just been exhibited in Paris. It is due to the generosity of the Fahnestock family of New York. It consists of twenty-two khaki-colored canvas tents. Eight conical tents are for the use of the staff. Six oblong tents are to be used for the wounded; each tent can receive eighteen so that there is a capacity of 108 wounded. Five hospital tents have a double covering, a circulation of air between the two layers of canvas maintaining an even temperature within the tents. Three of these five are for operation rooms; the fourth is used as a pharmacy and the fifth is for the reserve medical appliances. Three tents are intended each to accommodate two officers. These twenty-two tents and their contents are placed on four trucks furnished by the French government. To this unit, which is about to go to the front, are attached ten large automobiles belonging to the American hospital of Neuilly. Each of these cars can carry four or five wounded men sitting and three who are unable to sit up. The great utility of this ambulance will be in seeking out the wounded at the first aid post behind the line of fire and transporting them rapidly after the first dressings to the stations.

PHYSICIANS WHO HAVE RECEIVED THE DECORATION OF THE LEGION OF HONOR

Among the physicians serving in the army whose names have been inscribed on the roll of the Legion of Honor are a certain number of professors and agrégés of our medical schools. Two of these nominations deserve particular mention. Dr. Chavannaz, professor of clinical surgery at the Faculté de médecine de Bordeaux, head physician of the ambulance of the army corps "has insisted, in spite of his age, on performing campaign duty; he has rendered the greatest services to the wounded by his operative skill and his organizing talent." Dr. Paviot, professor of pathologic anatomy at the Faculté de médecine de Lyon, "has, since the beginning of hostilities, directed an evacuation hospital under difficult circumstances with a technical competence and an initiative which are equalled only by his absolute devotion to the service."

LONDON LETTER

London, June 4, 1915.

The War

GERMAN AIR RAIDS

German airships have dropped incendiary bombs on Southend, on the estuary of the Thames, causing fires which were promptly extinguished, but not without the loss of lives of several women and children. They also reached some of the outlying parts of London with a similar result. Four adults—three women and one old man—and two children have perished. The incendiary material used is "thermit," which was originally a mixture of equal parts of iron oxid and finely divided aluminum. This mixture may be ignited by a match of magnesium wire ending in a small quantity. When started in this manner, the ignition spreads through the whole of the mixture, reducing the iron oxid to metallic iron, with formation of aluminum oxid, and evolution of an amount of heat sufficient to melt the iron. Thermit has been largely used to weld wrought and cast-iron objects and to mend fractures in machinery, the operation being carried out by surrounding the point to be welded with a metallic box filled with thermit. Better results have been obtained by modifications of the original formula, in which powdered aluminum and calcium, or a powdered alloy of these two metals, are used instead of aluminum alone.

THE WAR MEDICAL SERVICE

In his presidential address to the General Medical Council, Sir Donald MacAlister reviewed the position created by the great demand for surgeons of the new armies. He pointed out that our professional reserves, at no time large, have been drawn on to the full. Throughout the kingdom, organized efforts are in progress for such readjustments of civil practice as will liberate all who can possibly be spared for the medical service of the navy and army. In these efforts, the Scottish Emergency Committee and local committees of the British Medical Association, with the effective cooperation of members of this council, have taken a leading part. The services of qualified women have been freely offered and accepted for many of the places that are now vacant at home. Senior students enrolled in the combatant ranks have been recalled by the War Office and directed to complete their curriculum with a view to qualification for the Royal Army Medical Corps. From overseas have come large numbers of our colonial colleagues, who are possessed of qualifications registerable in this country, and so are eligible for commissions in our army. Owing to a special regulation of the council, about sixty Belgian doctors of medicine have become legally qualified to practice in Britain and to occupy professional positions in public and other institutions. From all these sources we have obtained timely and valuable help, but they must be supplemented. If we are to make good the losses in the Army Medical Service we must accumulate larger reserves. The casualty lists and the lists also of awards for conspicuous gallantry testify to the magnitude of these losses. Inquiries as to the number of students actually in attendance on courses of medical study at the several schools show that, at the end of 1914, there were considerably over 1,000 fewer than in 1913. The recall of senior students from active service has had a favorable effect on the year now drawing to a close, but we must expect during the next few years a falling off of about 250 per annum in the number who become qualified as medical practitioners. Surgeons in Canada have been desirous of coming to the aid of the mother country, but have been hindered by difficulties connected with their local registration laws. Sir Donald MacAlister communicated with the various medical authorities concerned, and the response has exceeded all his expectations. From Ontario, British Columbia, Saskatchewan, Manitoba and Alberta came messages stating that legislation had already been initiated for the removal of existing provincial restrictions, and that the provinces desired that reciprocity with this country might be established at the earliest possible date. When the necessary steps are completed—and he has reason to think that no obstacles need be apprehended on this side of the Atlantic—all the provinces of Canada will have severally entered into reciprocal relations with the United Kingdom, the way will be open for the application of the medical act to the dominion as a whole, and the medical federation of the empire will be accomplished.

THE INCREASE OF WOMEN PHYSICIANS

The great increase in the number of women physicians in this country—from two, forty years ago, to over 1,000 at present—is reflected by the enlargement of the London School of Medicine for Women, at a cost of $100,000. Sixty new students will join the school in October, and the pressure on the space in the laboratory at which 220 are working is already very great. The increase in the number of women physicians was in progress before the war, but has been greatly accelerated by the shortage of men physicians produced by it.

INCREASE OF CANCER

The annual report for 1913 of the registrar-general, which has recently been published, unfortunately confirms the view that cancer is increasing. The deaths from this cause were greater in 1913 than in any previous year on record. The mortality among males was equal to 947 per million living, and among females to 1,155 per million, compared with rates of 913 and 117, respectively, in the year 1912. The tables show a constantly increasing mortality in proportion to urbanization, which is more serious in the case of males than females. According to the registrar-general, Dr. Stevenson, differences of the dimensions shown may be due to the better facilities for diagnosis in the urban areas, where a much larger proportion of the deaths occur in institutions in which postmortem examination is the rule, than, as in private practice, the exception. The considerable increase of mortality now recorded is very uniform, being common to the two sexes in every class of area. It is also widely spread over the different age periods, the chief exception being in the case of women at very advanced ages. The excess of female mortality over that of males is concentrated mainly on the ages from 25 to 55. At other ages there is either practical equality or a male excess, as at ages from 60 to 85 in the country generally. The increase of mortality from cancer of various organs differs. In both sexes the most rapid rates of increase are furnished by cancer of the alimentary tract, especially the intestines and stomach. Diseases of the female breasts also claim a rapidly increasing number of victims, while mortality from uterine cancer is diminishing. Childbearing appears to increase the risk of uterine and diminishes that of mammary cancer. The mortality from cancer of the liver remains stationary. Secondary growths are mentioned with especial frequency in cases of breast cancer. Deaths thus certified amount to 33 per cent. in the case of the breast, whereas in the case of most other important sites the proportion falls short of 10 per cent.

Marriages

WILBURN H. SMITH, M.D., to Mrs. Clara Rood Royce Akeley, both of Long Beach, Cal., at Santa Barbara, Calif., June 10.

FRANK HARMAN SMITH, M.D., Clintonville, Ky., to Miss Maude Hooser of Crowder, Okla., at Jeffersonville, Ind., June 2.

EDGAR FLOYD SEWELL, M.D., Somerville, Mass., to Miss Edna Florence Gordon of West Somerville, Mass., June 9.

MATTHEW HAMMOND GRISWOLD, M.D., Kensington, Conn., to Miss Vermadel Rodgers of Burlington, Vt., June 24.

JEREMIAH MILTON NEWMAN, M.D., Philadelphia, to Miss Ora Arneta Johnson of Richmond, Va., Dec. 2, 1914.

CLARKE JACKSON STALLWORTH, M.D., Thomaston, Ala., to Miss Mary Carter Adams, at Consul, Ala., May 19.

THOMAS GRIER MILLER, M.D., Philadelphia, to Miss Sarah H. George of Baltimore, in Philadelphia, June 3.

JOSEPH FRANCIS MELOAN, M.D., Media, Ill., to Miss Josephine Michael Block of Elsberry, Mo., June 1.

IRVING GEORGE WILTROUT, M.D., Swanville, Minn., to Miss Louise Schaefer of Two Rivers, Wis., June 5.

CHARLES MORGAN WILLIAMS, M.D., to Miss Jane Little Willison, both of Washington, N. J., June 8.

LEO ALBERT GOODMAN, M.D., Dubuque, Ia., to Miss Mary Cecelia Downey of Hammond, Ind., June 12.

THOMAS JEROME HENNEBERRY, M.D., Cheyenne, Wyo., to Miss Fredrika Dolcater, at Denver, June 2.

NORBERT CHARLES NITSCH, M.D., to Miss Ethel Marie Katzenberger, both of Baltimore, June 23.

CONSTANTINE J. MCGUIRE, JR., M.D., to Miss Alice M. Cordier, both of New York City, June 10.

CHARLES TAYLOR MOSS, M.D., Champaign, Ill., to Miss Lillian K. Christoph of Chicago, June 14.

CLYDE LE GRANDE SEITZ, M.D., to Miss Florence Elizabeth Heitshue, both of Glen Rock, Pa., June 2.

LOUIS F. MOLLEUR, M.D., to Mrs. Frank Reynolds, both of Melrose, Mont., in Butte, Mont., recently.

ELMER D. MADDUX, M.D., LaCrosse, Ind., to Miss Ethyle Schriver of York, Pa., in Chicago, June 3.

JAMES RUSSELL STEWART, M.D., to Miss Belle Williams, both of Colorado Springs, Colo., June 17.

THOMAS EDWARD CONLEY, M.D., Park Ridge, Ill., to Miss Ellen May Raynor of Chicago, June 21.

GEORGE TRAYLOR EDWARDS, M.D., Elba, Ala., to Miss Annie Lou Dudley of Mulberry, Ala., June 2.

FRANK MONTGOMERY, M.D., Denver, to Miss Claire Le Wallen of Manhattan, Kan., April 29.

JOSEPH IRVING LIND, M.D., New Haven, Conn., to Miss Stella A. Mann of Baltimore, June 7.

CHARLES CLEVELAND ADAMS, M.D., to Miss Madge Campbell, both of Longview, Tex., June 5.

JOHN WESLEY CLAYTON, M.D., Johnston City, Ill., to Miss Agnes Doty of Marion, Ill., June 2.

PAUL CLEMENTS, M.D., Culion, P. I., to Miss Trinidad Munoz, at Manila, P. I., April 11.

RUDOLPH E. J. ODEN, M.D., Cadillac, Mich., to Miss Olga Wahlquist of Minneapolis, June 8.

BURGOYNE H. GIBSON, M.D., Richmond, Ky., to Miss Mattie E. Lewis of Hyden, Ky., recently.

ANDREW SARGENT, M.D., Hopkinsville, Ky., to Miss Isabelle D. King of Philadelphia, May 5.

ROY ALVIN SCHNACKE, M.D., to Miss Thursnelda Abetmeyer, both of St. Paul, June 22.

GEORGE STANLEY BARBER, M.D., to Miss Alma Lucile Fain, both of Lawton, Okla., June 9.

CHARLES OTTO MOORE, M.D., to Miss Josephine Durkee, both of Salt Lake City, June 3.

WALTER SAULSBURY NIBLETT, M.D., to Miss Ethel Wolfe, both of Baltimore, June 9.

WILLIAM H. MARTIN, M.D., to Mrs. Anna P. Doyle, both of Houston, Tex., June 1.

HENRY JAMES, M.D., to Miss Rosalie O'Brien, both of New York City, June 8.

Deaths

Charles Edward Woodruff, M.D. Jefferson Medical College, 1886; lieutenant-colonel, U. S. Army (retired); who entered the Navy as assistant surgeon in 1866 and a year later transferred to the Medical Corps of the Army; an officer of distinguished service and awarded two medals for war service; author of several books and monographs, the best known of which are probably his work on, "The Effects of Tropical Light on White People," which appeared ten years ago, and his treatise on "Medical Ethnology," which appeared last month; a Fellow of the American Medical Association; assistant editor of *Modern Medicine;* died at his home in New Rochelle, N. Y., June 15, aged 54.

Charles Elihu Slocum, M.D. College of Physicians and Surgeons in the City of New York, 1869; Bellevue Hospital Medical College, 1876; Jefferson Medical College, 1876; at one time president of the Defiance County (Ohio) Medical Association and vice president of the District Medical Society; for several years professor of psychology and ethics in the Cleveland College of Physicians and Surgeons; at one time vice president of the Merchants' and First National banks at Defiance, Ohio; for many years a resident of Toledo; died in the Flower Hospital in that city, June 7, aged 74.

Jacob Michaux, M.D. Medical College of Virginia, Richmond, 1876; a member and once president of the Medical Society of Virginia and also president of the Richmond Academy of Medicine and Surgery; professor of materia medica and therapeutics in the University College of Medicine, Richmond, from its foundation in 1893 until 1912; assistant surgeon and later surgeon of the First Infantry, Virginia Volunteers; in 1889 appointed a member of the State Medical Board; one of the most prominent practitioners of Richmond; died at his home in that city, June 7, after a long illness, aged 63.

Abraham Barker Cates, M.D. Harvard Medical School, 1880; a Fellow of the American Medical Association and professor of obstetrics in the College of Medicine and Surgery of the University of Minnesota, Minneapolis; one of the leaders in the efforts in behalf of the Elliott Memorial University and the Trast Endowment; obstetrician to the Northwestern, Asbury and Swedish hospitals, Minneapolis, and attending physician to the Bethany Home; died at his summer home in Clearwater Lake, Minn., June 10, aged 61.

John Hildreth McCollom, M.D. Harvard Medical School, 1869; formerly a Fellow of the American Medical Association; a member of the Massachusetts Medical Society and American Society of Pathology and Bacteriology, and American Pediatric Society; emeritus professor of contagious diseases in his alma mater, and medical director of the Boston City Hospital; died at his home in Boston, June 13, aged 71.

Arthur Worrall Palmer, M.D. New York Homeopathic Medical College, New York City, 1883; surgeon and professor of laryngology at the New York Ophthalmic Hospital; laryngologist to the Metropolitan Hospital, New York City; formerly editor and publisher of the *Journal of Ophthalmology, Otology and Laryngology;* died at his home in New York City, June 10, aged 52.

Joseph Walker Floyd, M.D. Medical College of the State of South Carolina, Charleston, 1900; a member of the South Carolina Medical Association and Medical Society of the State of North Carolina; chairman of the board of trustees of the Tabor (N. C.) Graded School; a veteran of the Spanish-American War; died at his home in Tabor, June 4, from cerebral hemorrhage, aged 41.

Henry Janes, M.D. College of Physicians and Surgeons in the City of New York, 1855; a Fellow of the American Medical Association; surgeon of Volunteers during the Civil War in which he served as brevet lieutenant-colonel; at one time in command of the hospital ship *Maine*; and surgeon-general of the state of Vermont; died at his home in Waterbury, Vt., June 10, aged 82.

Henry Osborn Hanawalt, M.D. Medical College of Ohio, Cincinnati, 1873; professor of organic nervous diseases in the University of Kansas, School of Medicine; a veteran of the Civil War; at one time president of the Kansas Medical Society and the Jackson County (Mo.) Medical Society; died at his home in Kansas City, June 5, aged 70.

George B. Graves, M.D. University of the South, Sewanee, Tenn., 1903; formerly a member of the State Medical Association of Texas; formerly surgeon to the Virginia Pocahontas Coal Company, Coalwood, W. Va., and a member of the West Virginia State Medical Association; died at his home in Valentine, Tex., June 7, aged 34.

William Wabash Kneale, M.D. University of Virginia, Charlottesville, 1889; a member of the Indiana State Medical Association; for four years a member of the common council of Anderson, Ind.; physician to the American Steel and Wire Company; died at his home in Anderson, June 7, from cerebral hemorrhage, aged 54.

Lee Whitfield Staton, M.D. Kentucky School of Medicine, Louisville, 1879; of Richmond, Va.; acting assistant surgeon, U. S. P. H. S., for eighteen years; aged 58; a member of the Association of Military Surgeons of the United States; was thrown from his buggy, June 7, fracturing his skull and died fifteen minutes later.

James Small, M.D. American Medical College, Eclectic, St. Louis, 1880; resident physician to the Nuyaka Mission School, I. T., in 1890-1891; for many years a practitioner of north Arkansas, south Missouri and eastern Oklahoma; died at his home in Steedman, Okla., April 18, from pneumonia, aged 73.

Hal Laureston Speedy, M.D. Western Pennsylvania Medical College, Pittsburgh, 1911; formerly intern in St. John's Hospital, Pittsburgh, but for the last six months, assistant superintendent of the Santa Fe System hospital at Albuquerque, N. M.; died in Albuquerque, June 3, aged 29.

Maurice J. O'Connor, M.D. Northwestern University Medical School, Chicago, 1903; of Williams, Ia.; was crushed under his overturned automobile, near his home, June 7, and died a few hours later in St. Joseph's Mercy Hospital in Webster City, Ia., from his injuries, aged 38.

Powhattan Green Trent, M.D. Jefferson Medical College, 1867; a member of the Medical Association of the State of Alabama; formerly president of the Randolph County (Ala.) Board of Censors; died at his home in Roanoke, Ala., May 31, from heart disease, aged 70.

Amos T. Davis, M.D. Cincinnati College of Medicine and Surgery, 1859; formerly of Flat Rock, Ind.; died in his barrack at the National Home for Disabled Volunteer Soldiers, National Military Home, Ind., April 5, from acute dilatation of the heart, aged 79.

Edward Ellerslie Goodman, M.D. Jefferson Medical College, 1874; for forty years a practitioner of Altoona and at one time physician of Blair County; died at his home in Altoona, June 1, from cerebral hemorrhage, aged 65.

Thomas B. Ross, M.D. Washington University, St. Louis, 1866; a veteran of the Civil War and for thirty years a practitioner of Saline County, Mo.; died at his home in Slater, Mo., March 11, from sclerosis of the brain, aged 81.

James Edward Rankin, M.D. Keokuk (Ia.) Medical College, 1891; of Watertown, Ill.; died in the Watertown State Hospital, June 6, from the effects of poison, self-administered, it is believed, with suicidal intent, aged 46.

Ianthus G. Johnson, M.D. Albany (N. Y.) Medical College, 1853; for more than sixty years a practitioner of Greenfield Center, N. Y.; supervisor of the town of Greenfield for two years; died at his home, June 1, aged 85.

John Werton Hampton, M.D. Rush Medical College, 1912; of Norway, Mich.; physician for the Loretto (Mich.) Mining Company; died in St. Joseph's Hospital, Chicago, June 3, from lymphatic leukemia, aged 26.

Karl A. Norderling, M.D. College of Physicians and Surgeons, Chicago, 1887; formerly of Chicago, but since 1908 a resident of Paxton, Ill.; died at his home in that city, June 9, after a long illness, aged 58.

John Fullilove Taylor, M.D. Vermont Medical College, Woodstock, 1853; of Holly Grove, Ark.; a Confederate veteran; died at the home of his daughter in Little Rock, Ark., May 29, aged 81.

Edward F. Lake, M.D. Syracuse (N. Y.) University, 1882; of Denver; died at his home in that city, June 10, from malignant disease of the throat after an illness of more than two years, aged 55.

Daniel G. Allinder, M.D. University of Pennsylvania, Philadelphia, 1869; a veteran of the Civil War and formerly a practitioner of Pittsburgh; died in Washington, D. C., May 28.

William Henry Stettler, M.D. Bellevue Hospital Medical College, 1891; of Spinnerstown, Pa.; died in the German Hospital, Philadelphia, June 8, from strangulated hernia, aged 45.

Ross V. Dickey, M.D. Eclectic Medical Institute, Cincinnati, 1899; county physician of Allen County, Ohio; died at his home in Lima, June 9, from cerebral hemorrhage, aged 46.

John Tinsley Harrison, M.D. Atlanta (Ga.) Medical College, 1881; a member of the Medical Association of the State of Alabama; died at his home in Talladega, Ala., May 27, aged 81.

George Henry Hutchings, M.D. Eclectic Medical College of the City of New York, 1884; a practitioner for more than fifty years; died at his home in Woburn, Mass., May 30, aged 74.

Matthew Joseph McKenna, M.D. Long Island College Hospital, Brooklyn, 1912; Bay Ridge, Brooklyn; died at the home of his uncle in Brooklyn, June 4, from nephritis, aged 24.

George W. Loar, M.D. Physio-Medical Institute, Cincinnati, 1863; for nearly half a century a resident of Monroe, Ia.; died at his home, March 23, from pneumonia, aged 69.

William Webster Small, M.D. Ohio Medical College, Cincinnati, 1873; formerly of Indianapolis; died in Loomis, Calif., May 5, from chronic inflammation of the spleen, aged 64.

Alfred H. Metts (license, Indiana, 1897) of Fort Wayne, Ind.; a practitioner for nearly half a century; died suddenly in Ossian, Ind., June 4, from heart disease, aged 77.

Roy Earl Mauldin, M.D. Mississippi Medical College, Meridian, 1912; of Artesia, Miss.; aged 27, was shot and instantly killed by a druggist of that place, June 3.

John Blair Guthrie, M.D. University of Toronto, 1889; an advertising specialist of Illinois; died at his home in Evanston, Ill., June 5, from tuberculosis, aged 45.

Benedict Jones Wetherby, M.D. Rush Medical College, 1884; a Fellow of the American Medical Association; died at his home in Wilkes-Barre, Pa., May 28, aged 55.

John Gants, M.D. Eclectic Medical Institute, Cincinnati, 1872; for fifty-nine years a practitioner of Cromwell, Ind.; died at his home in that place, June 2, aged 82.

Orlando C. Stewart, M.D. University of Maryland, Baltimore, 1878; formerly of Cookport, Pa.; died at his home in Toledo, Ohio, June 2, from heart disease.

Samuel Elliott McCreary, M.D. Miami Medical College, Cincinnati, 1880; died in his office in Keokuk, Iowa, May 28, from cerebral hemorrhage, aged 58.

John Frederick Harrington, M.D. Keokuk (Iowa) Medical College, 1895; of Stacyville, Ia.; died in St. Francis' Hospital, Waterloo, Iowa, June 2, aged 53.

William P. Parr, M.D. Jefferson Medical College, 1859; died at his home in Wichita, Kan., April 6, from chronic diarrhea and rheumatism, aged 82.

M. D. Dunham, M.D. Chattanooga (Tenn.) Medical College, 1903; died at his home in Georgetown, Tenn., June 6, from heart disease, aged 60.

Thomas Burke Walsh, M.D. University of Illinois, Chicago, 1912; died at his home in Artesian, S. D., June 3, from heart disease, aged 30.

Franklin J. Clay Griffith, M.D. Cincinnati College of Medicine and Surgery, 1874; died at his home in Annapolis, Ill., May 27, aged 71.

Jesse Dwight Bacon, M.D. American Medical College, Cincinnati, 1856; died at his home in Cannelton, Ind., June 9, aged 83.

Isaac R. Landis, M.D. Jefferson Medical College, 1865; died at his home in Philadelphia, May 29, from nephritis, aged 74.

Isaac H. Kelly, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1880; died at his home in Stone Fort, Ill., May 27.

Joseph Prevett (license, Massachusetts, 1904), an Italian practitioner of Boston; died in Derry, N. H., June 6, aged 34.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

ARTICLES REFUSED RECOGNITION

Report of the Council on Pharmacy and Chemistry

Below appear abstracts of the Council's action on articles refused recognition which were not deemed of sufficient importance to require a lengthy report.

Venodine

Venodine (The Intravenous Products Co., Denver), according to information sent to the Council, is "an Intravenous Iodine Compound" put up in ampules each of which contains "28 grains of Sodium Iodide, ⅛ grain each of Beechwood Creosote and Guaiacol in a suitable vehicle, and excipients to enhance its compatibility with the circulating blood."

The "Therapeutic Indications" include "infectious diseases, such as syphilis, tuberculosis, bronchitis, bacteraemias associated with chronic and acute nephritis (Bright's disease), and other infections." The Council held as unwarranted and grossly exaggerated the following therapeutic claims: (1) that the full therapeutic value of iodin medication cannot be readily obtained except by intravenous injection; (2) that Venodine is "of exceptional value in tuberculosis"; (3) that in pneumonia Venodine "combines the anaesthetic properties of creosote and guaiacol with the germicidal value of iodine"; (4) that "Venodine (or its iodine component) has long enjoyed an exceptional reputation" as of great value in many infectious diseases including bacteremias. The facts on these points are the following:

1. Since iodids are easily absorbed from the mucous membrane of the gastro-intestinal tract and are usually well tolerated by the stomach, there is no reason for resorting to intravenous injection in their administration.
2. The indiscriminate administration of iodids for pulmonary tuberculosis is strongly to be condemned. The cases in which they can be given to tuberculous patients without doing harm must be very carefully selected.
3. There is no evidence either that creosote is excreted by the lungs in sufficient quantity to exert an anesthetic influence or that iodin is present in the circulation of the lungs or in the bronchial secretions in a form which is capable of exerting any germicidal action whatever.
4. It is generally held that the systemic administration of iodin compounds in bacteremias is useless.

The Council also held the name "Venodine" objectionable in that it fails to indicate the chief ingredient (sodium iodid) of this simple pharmaceutical mixture. The statement in a circular that "Venodine is a sterile solution representing 1.54 Gm. (24 grains) of iodine in chemical combination together with creosote and guaiacol" is likely to lead physicians to use the preparation without considering that its chief constituent is the well-known substance sodium iodid, particularly so since no reference to sodium iodid is made in the circular.

Furthermore, the Council held that the combination of two such similar substances as creosote and guaiacol (the second a constituent of the first) as given in the published formula, stamps Venodine as unscientific; it adds mystery to the preparation, but does not increase its efficiency, and is therefore against the best interests of the public.

The Council voted that Venodine be held ineligible for conflict with Rules 6, 8 and 10.

This report having been submitted to the manufacturers, in accordance with the Council's custom, and the reply affording no reason for modifying the findings, its publication has now been authorized.

Calcreose

In response to inquiries and in view of the extensive advertising propaganda, the Council, on Dec. 19, 1913, took up for consideration Calcreose (Maltbie Chemical Company, Newark, N. J.). Examination showed that the preparation contained, in loose combination, approximately equal weights of creosote and lime. The claims made in the advertising "literature" were extravagant and uncritical, and the Council therefore held Calcreose ineligible for New and Nonofficial Remedies.

In June, 1914, at the request of the Maltbie Chemical Company, the Council undertook a reconsideration of the preparation. The advertising claims were now found more conservative. Before the existing claims could be judged, however, the Council deemed it necessary to require from the company satisfactory proof (1) that the large doses of Calcreose recommended and administered actually furnish large amounts of creosote to the blood, and (2) that patients taking these large doses do not suffer from digestive disturbances, loss of nutrition, albumin in the urine or phenol urine, as claimed. The Council accordingly advised the company of this requirement, at the same time stipulating that nothing in the report should be interpreted as indicating a belief on the part of the Council that enormous doses of creosote are necessary for, or will promote a cure of tuberculosis.

The Maltbie Chemical Company has not up to the present date furnished this proof, but has evinced a disposition to make the Council's holding Calcreose under advisement appear in the guise of a quasi-approval. It is therefore recommended that Calcreose be refused recognition for conflict with Rule 6.

Standard Radium Solution for Intravenous Use

Standard Radium Solution for Intravenous Use (Radium Chemical Co., Pittsburgh) is sold in ampules each containing radium bromid equivalent to 0.05 microgram radium element and 0.0002 gm. or less of barium bromid dissolved in 2 c.c. sterile normal physiologic salt solution.

While the Council has confirmed the claimed composition of Standard Radium Solution for Intravenous Use so far as concerns the radium content, it refused recognition to the preparation because there is no clear evidence that intravenous injection has any advantage over the other methods of administering radium. The Council holds that radium for internal medical use is in an experimental stage, that, on the basis of our present knowledge, this substance should be used intravenously only by those in a position to study its effect carefully, and in an institution equipped with the necessary facilities for such study. For these reasons and on account of the risk involved with any form of intravenous medication, the Council voted not to accept Standard Radium Solution for Intravenous Use for inclusion with New and Nonofficial Remedies.

In accordance with the Council's regular procedure this report was submitted to the Radium Chemical Company for comment. The Council, after considering the new evidence offered, decided that its previous action should be allowed to stand and accordingly authorized publication.

Rheumalgine

Rheumalgine (Eli Lilly & Co., Indianapolis) is put up both in tablet form and as a liquid. Each tablet, or teaspoonful of the liquid, is said to contain:

"Strontium salicylate from Natural Oil	5 gr.
Hexamethylenamin	2 gr.
Colchicine	1/200 gr."

The advertising matter contains several statements regarding the individual ingredients to which objection must be made.

It is claimed (quoting from Hare) that strontium salicylate

> ". . . is not so disagreeable to the taste as the corresponding sodium salts, and more important still, it is far less apt to disorder the stomach."

"Taste" is a difficult subject to dispute; but in the experience of the referee patients object more to the strontium than to the sodium salt. No evidence is submitted to prove that the strontium salt is less apt to disorder the stomach. In observations made under the direction of the referee, the nauseant and emetic doses are about the same as, or even less than, those of sodium salicylate.

Under hexamethylenamin, the recommendations are not confined to its recognized use as a urinary antiseptic; it is also said to be "unexcelled" as a "germicide," and to prevent the formation of urate and phosphate deposits. These statements are contrary to facts.

> "Rheumalgine . . . may be used in all cases where the salicylates are indicated. It is superior to preparations containing sodium salicylate, in that it does not cause nausea or disturb the digestion."

Both the preceding statements are misleading. The necessity of giving 1/200 grain of colchicin for each 5 grains of salicylate would certainly interfere with the use of adequate doses of the latter. The colchicin would produce digestive disturbance quite apart from the salicylate.

The mixture is described as:

> ". . . ANTIRHEUMATIC, ANTIPYRETIC, URINARY ANTISEPTIC, AND URIC ACID ELIMINANT. Useful in Acute Articular and Chronic Rheumatism, Muscular Pains, Lumbago, Sciatica, Migraine of the Rheumatic, Gout, and in Nervous Irritability of the Gouty or Lithemic."

The facts are: Salicylates are useful in some of these conditions, colchicin occasionally in a few, hexamethylenamin in none. The combination is conducive to uncritical prescribing. For instance, salicylates are effective in acute articular rheumatism; hexamethylenamin and colchicin are useless; salicylates are of very little use in chronic rheumatism, sciatica and nervous irritability, while hexamethylenamin and colchicin are useless in these conditions; colchicin is sometimes effective in gout, salicylates perhaps also; hexamethylenamin is not.

Attention should also be called to the high dosage of colchicin, namely, 1/100 to 1/50 of a grain of the alkaloid, every three or four hours, the dose then to be "slightly reduced," but continued for several days; or in chronic cases, 1/100 to 1/30 grain per day, continued indefinitely. This dosage appears high, if a really active preparation is used.

Finally, the name "Rheumalgine" encourages thoughtless and unscientific prescribing. If a mixture is used at all, the prescriber should be constantly reminded of its composition.

It is therefore recommended that Rheumalgine be held in conflict with Rules 6 (unwarranted therapeutic claims), 8 (non-descriptive name) and 10 (unscientific composition).

Correspondence

Cancer and Heredity

To the Editor:—In Dr. Slye's recent communication (The Incidence and Inheritability of Spontaneous Cancer in Mice. *Jour. Med. Research,* 1915, xxxii, 159) concerning the inheritance of cancer, reference is made by way of illustration to a type-color inheritance which, since it is quite contrary to the more generally accepted principles of mendelian inheritance, requires critical comment.

On page 160 she says, "Let me at this point recall some of the basic facts of heredity." She then proceeds, using the customary mendelian terms "dominant" and "recessive," to describe a cross between *gray and albino mice,* and indicates results which are incompatible with those of other investigators. She furthermore furnishes no data in support of this more or less revolutionary hypothesis.

As Castle, Allen, Bateson, Durham, Cuenot, Plate, Davenport, and many others have carried on investigations on this particular problem in genetics and have reached results contrary to those predicted by Slye, it seems reasonable to demand a full presentation of her data on the inheritance of *albinism* in mice. In fact, a careful repetition of such work should be expected before her claims are to be accepted.

To those unfamiliar with the work of the geneticists above mentioned, Slye's paper might be taken as presenting the well-known principles of mendelian inheritance. With a knowledge of the facts, however, it is obvious that the type of inheritance which she outlines has not been observed in similar material by any of the investigators above mentioned. That this discrepancy is not based on an oversight on the part of Miss Slye has been determined by personal correspondence.

C. C. Little, Boston.

Cancer Commission of Harvard University.

[The foregoing letter was referred to Dr. Slye who writes:]

To the Editor:—Dr. Little's criticism is of course concerned wholly with a dispute on questions of mendelian interpretation. Such a dispute in no way affects the validity of my results in cancer. Unfortunately, at the present time there is so much difference of opinion on almost every point in the mendelian doctrines that one could scarcely put out any results which would satisfy all the adherents of the different hypotheses.

The production of about a thousand spontaneous cancers in specified strains, and the nonoccurrence among this entire number of any cancer in certain other specified strains, no matter what test is applied to them, demonstrates to every reasonable probability the inheritability of cancer, and when these results are characteristically and systematically obtained in such an immense stock as to furnish over 10,000 necropsies and a living stock of about 11,000 mice, with a steady production of between seventy-five and a hundred cancer patients all the time and almost without exception within proved cancer strains, this reasonable probability is raised to an almost indisputable fact; and whether or not my strains of house mice have behaved in hybrid crosses in accordance with the established canon has no bearing whatever on the behavior of cancer. This question lies in quite another field.

In regard to my use of the terms "dominant" and "recessive" with respect to cancer behavior: It is almost the established conviction today that these terms are descriptive and not dynamic, and they furnish in the description of the behavior of cancer in heredity a graphic and convenient tool. That is probably all they furnish in the exposition of any problem in heredity. They may be discarded for even that service within the next few years.

The chief value in the study of cancer of the use of a partial mendelian background of comparison (although the details may be under dispute) is to show to those most interested how far back in a strain cancer may lie and still be transmitted, and by what sorts of crosses this can be done; and to make it plain that in deciding on the inheritability of human cancer and of the method of elimination of cancer from a family, one cannot take as a criterion of judgment whether or not the immediate parents exhibited cancer.

I do not desire or make a strict mendelian interpretation of my results; indeed, I should deplore such an interpretation. I have used mendelian comparisons (1) to make clear the influence of a more or less remote ancestry on later generations of progeny; (2) to show how cancer, like albinism, has been transmitted in my strains through generation after generation *by individuals who did not exhibit it;* and (3) to demonstrate how cancer thus transmitted finally leaps into expression in the offspring of a pair neither of whom expresses cancer, but both of whom bear it potentially.

The approximation even to conservative mendelian results is strikingly close for such a characteristic as cancer.

Maud Slye, Chicago.
The Otho S. A. Sprague Memorial Institute.

The Notary Fee in Applications for License Under the Harrison Narcotic Law

To the Editor:—I have just received notice from the collector of internal revenue that my application for a license, under the Harrison Narcotic Law, must be sworn to before a notary before it is sent to him.

It seems to me that we ought to make a strong protest against this very unjust rule. The fee for this service is from twenty-five to fifty cents, depending on the location. Usually it is fifty cents, which is not a very large sum; but in the aggregate it will amount to many thousands of dollars, and for what good? Absolutely none, except for the notary.

We have all complied with the law, and our licenses were duly paid for and issued for the four remaining months of the fiscal year. No notary fees were required for that. Every physician in the country entitled to use, prescribe or dispense any drug coming under the law is on record at his respective collector's office. The penalty for violation of the law in any way is very severe; therefore, why this unjust fee?

Henry F. Hoyt, M.D., Long Beach, Calif.

Kaolin, Clay Eaters and Clay-Containing Streams

To the Editor:—Noting in The Journal of June 12 editorial and other reference to the subject of the adsorption, perhaps by virtue of colloidal states of solution, by kaolin, I write to suggest that, in light of the work on its effect on the intestinal bacteria, investigations of the peculiar physiologic or pathologic state of the "clay eaters," numerous in some localities (North Carolina mountains) would be interesting. Especially would this be interesting in connection with the thought and the slight amount of experimental evidence of the possibility of life without the ingestion or the presence in the intestinal canal of micro-organisms.

Entirely aside from all but its physicochemical bearing is the curious condition of the river waters in many of the Southern streams. Even when practically motionless, they seem to hold in suspension indefinitely the whole or a considerable part of the finely divided clay particles of the soil of the territories which they drain. Much attention has for years been devoted to the fluvial waters and drinking water generally by the Italians, lately especially in connection with the etiology of pellagra. It might be that a study of the questions involved would result in considerable advance in our knowledge of many obscure problems of intestinal metabolism.

Jonathan Wright, M.D., Pleasantville, N. Y.

A "Twilight Sleep" Exhibit

To the Editor:—We have recently had presented in our city films representing "twilight sleep," accompanied by a lecture by a "German doctor." It purports to be under the auspices of the "Motherhood Educational Society." A committee of the Civic League of Saginaw, after seeing it in Bay City, protested against its presentation here—vainly, however, as the mayor found nothing objectionable in either pictures or lecture, and rebuked the women who objected to the commercial exploitation of maternity.

The lecturer subtly attacked the medical profession throughout. At the close, he invites questions from the audience. A good opportunity to test the reaction of the production is thus afforded. Some of the questions were offensive; on these the lecturer waxed witty, and there was hilarity in a considerable part of the audience. Aside from the question of bad taste, his statements were absolutely untrue. He claimed that twilight sleep was successful in 90 per cent. of all maternity cases.

What can be done to prevent such mischievous presentations to mixed audiences?

I have read with interest The Journal of May 22 with its reports of scopolamin-morphin treatment. In the light of such reports, a production such as was presented here is misleading and harmful in every way.

Mrs. Elizabeth S. Curtis,
The Civic League, Saginaw, Mich.

Possibility of Failure in Prophylactic Typhoid Vaccination

To the Editor:—The following case is instructive from the standpoint of surgical diagnosis:

Miss X, aged 21 years, a nurse in Hahnemann Hospital, complained of anorexia and malaise for three days, at the end of which time she was suddenly taken with general abdominal pains. There was neither nausea nor vomiting. Her temperature was 102.4 F., pulse 120 and respirations 20. The white cell count was 12,000. The next morning, Dec. 27, 1914, the temperature was 103 F., the pulse 118, and pain and tenderness were localized in the right iliac fossa. Inquiry developed the fact that she had previously received immunizing injections of typhoid vaccine in another hospital as follows: Oct. 12, 1914, 500 million; Oct. 22, 1914, 1,000 million; Nov. 2, 1914, 1,000 million. The first dose was administered by the resident physician, the second by the supervising nurse and the third by a nurse in training. No ill effects whatever were experienced from the injections. In view of "literature" were extravagant and uncritical, and the Council therefore held Calcreose ineligible for New and Nonofficial Remedies.

In June, 1914, at the request of the Maltbie Chemical Company, the Council undertook a reconsideration of the preparation. The advertising claims were now found more conservative. Before the existing claims could be judged, however, the Council deemed it necessary to require from the company satisfactory proof (1) that the large doses of Calcreose recommended and administered actually furnish large amounts of creosote to the blood, and (2) that patients taking these large doses do not suffer from digestive disturbances, loss of nutrition, albumin in the urine or phenol urine, as claimed. The Council accordingly advised the company of this requirement, at the same time stipulating that nothing in the report should be interpreted as indicating a belief on the part of the Council that enormous doses of creosote are necessary for, or will promote a cure of tuberculosis.

The Maltbie Chemical Company has not up to the present date furnished this proof, but has evinced a disposition to make the Council's holding Calcreose under advisement appear in the guise of a quasi-approval. It is therefore recommended that Calcreose be refused recognition for conflict with Rule 6.

Standard Radium Solution for Intravenous Use

Standard Radium Solution for Intravenous Use (Radium Chemical Co., Pittsburgh) is sold in ampules each containing radium bromid equivalent to 0.05 microgram radium element and 0.0002 gm. or less of barium bromid dissolved in 2 c.c. sterile normal physiologic salt solution.

While the Council has confirmed the claimed composition of Standard Radium Solution for Intravenous Use so far as concerns the radium content, it refused recognition to the preparation because there is no clear evidence that intravenous injection has any advantage over the other methods of administering radium. The Council holds that radium for internal medical use is in an experimental stage, that, on the basis of our present knowledge, this substance should be used intravenously only by those in a position to study its effect carefully, and in an institution equipped with the necessary facilities for such study. For these reasons and on account of the risk involved with any form of intravenous medication, the Council voted not to accept Standard Radium Solution for Intravenous Use for inclusion with New and Nonofficial Remedies.

In accordance with the Council's regular procedure this report was submitted to the Radium Chemical Company for comment. The Council, after considering the new evidence offered, decided that its previous action should be allowed to stand and accordingly authorized publication.

Rheumalgine

Rheumalgine (Eli Lilly & Co., Indianapolis) is put up both in tablet form and as a liquid. Each tablet, or teaspoonful of the liquid, is said to contain:

"Strontium salicylate from Natural Oil	5 gr.
Hexamethylenamin	2 gr.
Colchicine	1/200 gr."

The advertising matter contains several statements regarding the individual ingredients to which objection must be made.

It is claimed (quoting from Hare) that strontium salicylate

> ". . . is not so disagreeable to the taste as the corresponding sodium salts, and more important still, it is far less apt to disorder the stomach."

"Taste" is a difficult subject to dispute; but in the experience of the referee patients object more to the strontium than to the sodium salt. No evidence is submitted to prove that the strontium salt is less apt to disorder the stomach. In observations made under the direction of the referee, the nauseant and emetic doses are about the same as, or even less than, those of sodium salicylate.

Under hexamethylenamin, the recommendations are not confined to its recognized use as a urinary antiseptic; it is also said to be "unexcelled" as a "germicide," and to prevent the formation of urate and phosphate deposits. These statements are contrary to facts.

> "Rheumalgine . . . may be used in all cases where the salicylates are indicated. It is superior to preparations containing sodium salicylate, in that it does not cause nausea or disturb the digestion."

Both the preceding statements are misleading. The necessity of giving 1/200 grain of colchicin for each 5 grains of salicylate would certainly interfere with the use of adequate doses of the latter. The colchicin would produce digestive disturbance quite apart from the salicylate.

The mixture is described as:

> ". . . ANTIRHEUMATIC, ANTIPYRETIC, URINARY ANTISEPTIC, AND URIC ACID ELIMINANT. Useful in Acute Articular and Chronic Rheumatism, Muscular Pains, Lumbago, Sciatica, Migraine of the Rheumatic, Gout, and in Nervous Irritability of the Gouty or Lithemic."

The facts are: Salicylates are useful in some of these conditions, colchicin occasionally in a few, hexamethylenamin in none. The combination is conducive to uncritical prescribing. For instance, salicylates are effective in acute articular rheumatism; hexamethylenamin and colchicin are useless; salicylates are of very little use in chronic rheumatism, sciatica and nervous irritability, while hexamethylenamin and colchicin are useless in these conditions; colchicin is sometimes effective in gout, salicylates perhaps also; hexamethylenamin is not.

Attention should also be called to the high dosage of colchicin, namely, 1/100 to 1/50 of a grain of the alkaloid, every three or four hours, the dose then to be "slightly reduced," but continued for several days; or in chronic cases, 1/100 to 1/30 grain per day, continued indefinitely. This dosage appears high, if a really active preparation is used.

Finally, the name "Rheumalgine" encourages thoughtless and unscientific prescribing. If a mixture is used at all, the prescriber should be constantly reminded of its composition.

It is therefore recommended that Rheumalgine be held in conflict with Rules 6 (unwarranted therapeutic claims), 8 (non-descriptive name) and 10 (unscientific composition).

Correspondence

Cancer and Heredity

To the Editor:—In Dr. Slye's recent communication (The Incidence and Inheritability of Spontaneous Cancer in Mice. *Jour. Med. Research,* 1915, xxxii, 159) concerning the inheritance of cancer, reference is made by way of illustration to a type-color inheritance which, since it is quite contrary to the more generally accepted principles of mendelian inheritance, requires critical comment.

On page 160 she says, "Let me at this point recall some of the basic facts of heredity." She then proceeds, using the customary mendelian terms "dominant" and "recessive," to describe a cross between *gray and albino mice,* and indicates results which are incompatible with those of other investigators. She furthermore furnishes no data in support of this more or less revolutionary hypothesis.

As Castle, Allen, Bateson, Durham, Cuenot, Plate, Davenport, and many others have carried on investigations on this particular problem in genetics and have reached results contrary to those predicted by Slye, it seems reasonable to demand a full presentation of her data on the inheritance of *albinism* in mice. In fact, a careful repetition of such work should be expected before her claims are to be accepted.

To those unfamiliar with the work of the geneticists above mentioned, Slye's paper might be taken as presenting the well-known principles of mendelian inheritance. With a knowledge of the facts, however, it is obvious that the type of inheritance which she outlines has not been observed in similar material by any of the investigators above mentioned. That this discrepancy is not based on an oversight on the part of Miss Slye has been determined by personal correspondence.

C. C. Little, Boston.

Cancer Commission of Harvard University.

[The foregoing letter was referred to Dr. Slye who writes:]

To the Editor:—Dr. Little's criticism is of course concerned wholly with a dispute on questions of mendelian interpretation. Such a dispute in no way affects the validity of my results in cancer. Unfortunately, at the present time there is so much difference of opinion on almost every point in the mendelian doctrines that one could scarcely put out any results which would satisfy all the adherents of the different hypotheses.

The production of about a thousand spontaneous cancers in specified strains, and the nonoccurrence among this entire number of any cancer in certain other specified strains, no matter what test is applied to them, demonstrates to every reasonable probability the inheritability of cancer, and when these results are characteristically and systematically obtained in such an immense stock as to furnish over 10,000 necropsies and a living stock of about 11,000 mice, with a steady production of between seventy-five and a hundred cancer patients all the time and almost without exception within proved cancer strains, this reasonable probability is raised to an almost indisputable fact; and whether or not my strains of house mice have behaved in hybrid crosses in accordance with the established canon has no bearing whatever on the behavior of cancer. This question lies in quite another field.

In regard to my use of the terms "dominant" and "recessive" with respect to cancer behavior: It is almost the established conviction today that these terms are descriptive and not dynamic, and they furnish in the description of the behavior of cancer in heredity a graphic and convenient tool. That is probably all they furnish in the exposition of any problem in heredity. They may be discarded for even that service within the next few years.

The chief value in the study of cancer of the use of a partial mendelian background of comparison (although the details may be under dispute) is to show to those most interested how far back in a strain cancer may lie and still be transmitted, and by what sorts of crosses this can be done; and to make it plain that in deciding on the inheritability of human cancer and of the method of elimination of cancer from a family, one cannot take as a criterion of judgment whether or not the immediate parents exhibited cancer.

I do not desire or make a strict mendelian interpretation of my results; indeed, I should deplore such an interpretation. I have used mendelian comparisons (1) to make clear the influence of a more or less remote ancestry on later generations of progeny; (2) to show how cancer, like albinism, has been transmitted in my strains through generation after generation *by individuals who did not exhibit it;* and (3) to demonstrate how cancer thus transmitted finally leaps into expression in the offspring of a pair neither of whom expresses cancer, but both of whom bear it potentially.

The approximation even to conservative mendelian results is strikingly close for such a characteristic as cancer.

Maud Slye, Chicago.
The Otho S. A. Sprague Memorial Institute.

The Notary Fee in Applications for License Under the Harrison Narcotic Law

To the Editor:—I have just received notice from the collector of internal revenue that my application for a license, under the Harrison Narcotic Law, must be sworn to before a notary before it is sent to him.

It seems to me that we ought to make a strong protest against this very unjust rule. The fee for this service is from twenty-five to fifty cents, depending on the location. Usually it is fifty cents, which is not a very large sum; but in the aggregate it will amount to many thousands of dollars, and for what good? Absolutely none, except for the notary.

We have all complied with the law, and our licenses were duly paid for and issued for the four remaining months of the fiscal year. No notary fees were required for that. Every physician in the country entitled to use, prescribe or dispense any drug coming under the law is on record at his respective collector's office. The penalty for violation of the law in any way is very severe; therefore, why this unjust fee?

Henry F. Hoyt, M.D., Long Beach, Calif.

Kaolin, Clay Eaters and Clay-Containing Streams

To the Editor:—Noting in The Journal of June 12 editorial and other reference to the subject of the adsorption, perhaps by virtue of colloidal states of solution, by kaolin, I write to suggest that, in light of the work on its effect on the intestinal bacteria, investigations of the peculiar physiologic or pathologic state of the "clay eaters," numerous in some localities (North Carolina mountains) would be interesting. Especially would this be interesting in connection with the thought and the slight amount of experimental evidence of the possibility of life without the ingestion or the presence in the intestinal canal of micro-organisms.

Entirely aside from all but its physicochemical bearing is the curious condition of the river waters in many of the Southern streams. Even when practically motionless, they seem to hold in suspension indefinitely the whole or a considerable part of the finely divided clay particles of the soil of the territories which they drain. Much attention has for years been devoted to the fluvial waters and drinking water generally by the Italians, lately especially in connection with the etiology of pellagra. It might be that a study of the questions involved would result in considerable advance in our knowledge of many obscure problems of intestinal metabolism.

Jonathan Wright, M.D., Pleasantville, N. Y.

A "Twilight Sleep" Exhibit

To the Editor:—We have recently had presented in our city films representing "twilight sleep," accompanied by a lecture by a "German doctor." It purports to be under the auspices of the "Motherhood Educational Society." A committee of the Civic League of Saginaw, after seeing it in Bay City, protested against its presentation here—vainly, however, as the mayor found nothing objectionable in either pictures or lecture, and rebuked the women who objected to the commercial exploitation of maternity.

The lecturer subtly attacked the medical profession throughout. At the close, he invites questions from the audience. A good opportunity to test the reaction of the production is thus afforded. Some of the questions were offensive; on these the lecturer waxed witty, and there was hilarity in a considerable part of the audience. Aside from the question of bad taste, his statements were absolutely untrue. He claimed that twilight sleep was successful in 90 per cent. of all maternity cases.

What can be done to prevent such mischievous presentations to mixed audiences?

I have read with interest The Journal of May 22 with its reports of scopolamin-morphin treatment. In the light of such reports, a production such as was presented here is misleading and harmful in every way.

Mrs. Elizabeth S. Curtis,
The Civic League, Saginaw, Mich.

Possibility of Failure in Prophylactic Typhoid Vaccination

To the Editor:—The following case is instructive from the standpoint of surgical diagnosis:

Miss X, aged 21 years, a nurse in Hahnemann Hospital, complained of anorexia and malaise for three days, at the end of which time she was suddenly taken with general abdominal pains. There was neither nausea nor vomiting. Her temperature was 102.4 F., pulse 120 and respirations 20. The white cell count was 12,000. The next morning, Dec. 27, 1914, the temperature was 103 F., the pulse 118, and pain and tenderness were localized in the right iliac fossa. Inquiry developed the fact that she had previously received immunizing injections of typhoid vaccine in another hospital as follows: Oct. 12, 1914, 500 million; Oct. 22, 1914, 1,000 million; Nov. 2, 1914, 1,000 million. The first dose was administered by the resident physician, the second by the supervising nurse and the third by a nurse in training. No ill effects whatever were experienced from the injections. In view of these past facts and present symptoms, the case was diagnosed appendicitis, and operation performed. The findings in the appendix did not satisfy the diagnosis, and the case was closely watched. The temperature continued between 103 and 104 F. and the pulse above 110. December 28, the leukocytes were 11,600. December 29, a blood culture in glucose bouillon was negative. December 31, the Widal reaction, as was anticipated from the previous immunization, was positive. December 31, a second blood culture in bile was positive for the typhoid bacillus. Jan. 4, 1915, the leukocytes were 5,400, and rose spots appeared. The patient ran an average typhoid course, without complications, to recovery.

While the value and efficacy of typhoid immunization are undisputed and difficult to overrate, and while occurrences as cited are probably very rare, the foregoing experience may be timely and valuable in emphasizing the fallacy which seems to prevail in medical circles, namely, that recent typhoid immunization entirely eliminates typhoid fever in questions of abdominal diagnosis. The great mass of conclusive figures in favor of prophylactic typhoid vaccination are apt to blind us to the possibility of its failure in a certain very small percentage of cases for reasons which should be carefully inquired into.

S. W. Sappington, M.D., Philadelphia.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

POSTSACRAL SINUS

To the Editor:—As I have been unable to find anything in the books at my disposal, I should consider it a favor if you would give me some information on postsacral sinus, its etiology, pathology, prognosis and treatment.

C. C. I.

Answer.—The term "postsacral sinus" has no specific meaning, as a sinus in the postsacral region may be due to a variety of causes as, for instance, osteomyelitis of the sacrum or coccyx of tuberculous or other origin; tuberculosis of the sacro-iliac joint, or of the hip, etc. Excluding bone or joint trouble of this kind, the most frequent cause of a sinus in this region is a persistence of the blastopore, or neurenteric canal, one of the earliest fetal canals extending from the surface of the embryo near the caudal end to the notochord.

This canal usually entirely disappears at a very early period of fetal life. There is almost always a small dimple in the lower sacral or coccygeal region which marks the point of the blastopore. Occasionally the blastopore fails to disappear entirely, a small tract of varying length remaining lined with epithelium. This little tract may be closed on the surface, in which case a small cyst may develop filled with sebaceous material. The cyst may become inflamed, open and discharge the sebaceous material, when a little sinus will persist.

Again, the blastopore may fail to close, in which case an epithelial-lined sinus of congenital origin may be present; or the tract may open on the surface at some later time of life, and a sinus persist. A similar condition is occasionally found at the umbilicus, because of a persistence of the omphalomesenteric duct.

The proper treatment of these sinuses is simply to remove the epithelium-lined tract.

BURNS OF THE EYE FROM LIME

To the Editor:—Please give the most approved method of treatment for the common and serious accident of getting lime in the eye. I have known several persons who have lost their eyesight completely from this accident, and I have been unable to find a book that even touches the treatment in a case of this kind.

F. E. P.

Answer.—This form of accident occurs quite frequently, and is apt to be followed by very grave results. The most serious and important sequel is the adherence of the lid to the globe (symblepharon) when there are two opposing raw surfaces. If the patient is seen immediately after the accident, the first step in the treatment is to drop into the conjunctival sac a few drops of a 1 per cent. solution of holocain, or of a 4 per cent. solution of cocain, in order to relieve the pain, which is usually intense, and then to remove all the remaining particles of lime as quickly as possible. The irrigating fluid should be a weak solution of vinegar, to neutralize the caustic effect of the lime. Subsequently cold applications should be applied to the closed lids, and a mild antiseptic, such as a 3 per cent. boric acid solution, dropped into the eye every two or three hours. If the burn is at all extensive, the conjunctival sac should be filled with an antiseptic ointment, which not only relieves the pain, but also prevents adhesion of the opposing surfaces. One of the best preparations for this purpose is a mercuric chlorid ointment which consists of mercuric chlorid (1 : 10,000) in petrolatum. Severe burns from lime, resulting in complete opacity of the cornea, have been treated—in addition to the usual local treatment—by subcutaneous injections of sodium cacodylate (from 3 to 7 grains at a dose) with perfect results. For the general practitioner who, in emergencies like this, should be prepared to treat conditions which ordinarily belong to the ophthalmic surgeon, a practical book is "The Commoner Diseases of the Eye," by Wood and Woodruff. It takes up only the diseases of the eye most frequently seen, and how to detect and treat them, without technical discussion.

REFERENCES ON DISEASE OF THE PITUITARY GLAND

To the Editor:—I want to find out all I can concerning the effect of disease of the pituitary gland. Does this gland have any effect on the growth of the body? I am particularly interested in the case of a boy, aged 17, who weighs 217 pounds, and is 6 feet 5 inches tall. The parents for three generations have been normal, and average 5 feet 8 inches in height.

J. T. Gray, M.D., Stillwater, Okla.

Answer.—The following is a list of references concerning disease of the pituitary gland:

DENTAL CLINICS

To the Editor:—In the *Washington Medical Annals*, January, 1915, there was published an article on school clinics, which I wrote, based on information gathered by the U. S. Bureau of Education. This article contains the names of all communities having school clinics, and shows that at the time when the statistics were gathered (up to October, 1914) forty-six communities had clinics for treating the teeth of schoolchildren; since that time Pittsburgh has also established school clinics for the eyes and teeth. This is in reply to the inquiry of R. B. (The Journal, May 22, 1915, p. 1782).

George H. Heitmuller, M.D., Washington, D. C.

Missouri March Report

Dr. J. A. B. Adcock, secretary of the Missouri State Board of Health, reports the oral and written examination held at St. Louis, March 22-24, 1915. The total number of subjects examined in was 14; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 26, of whom 20 passed and 6 failed. Five candidates were granted reregistration licenses. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
University of Arkansas	(1913)	84.2
Bennett Medical College	(1914)	85.6
College of Physicians and Surgeons, Chicago	(1893)	75
Rush Medical College	(1913) 90.7; (1914)	87.5, 85.2
Tufts College Medical School	(1905)	80.2
American Medical College	(1914)	77.9, 82.4, 90
St. Louis College of Phys. and Surgs.	(1908) 77.5; (1914)	75.8, 76.6
Washington University	(1904)	83.7
University and Bellevue Hospital Medical College	(1914)	88.8
Meharry Medical College	(1904)	75
University of West Tennessee	(1914)	76, 78.9, 82.1
Fort Worth School of Medicine	(1906)	75
FAILED		
American Medical College	(1914)	72.3
St. Louis College of Phys. and Surgs.	(1910) 69.1; (1914)	71.5
University of West Tennessee	(1914)	70.8, 73.2, 73.5

Colorado April Report

Dr. David A. Strickler, secretary of the Colorado State Board of Medical Examiners, reports the oral and written examination held at Denver, April 6, 1915. The total number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 75. The total number of candidates examined was 4, of whom 3 passed, including 1 osteopath, and 1 failed. Eleven candidates were licensed through reciprocity. One candidate was granted a reregistration license. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
University of Louisville	(1914)	88.1
John A. Creighton Medical College	(1914)	81.6
FAILED		
Tokyo Charity Hosp. College, Japan*	(1911)	58.5

* Not included in the official list of foreign medical colleges prepared by the Council on Medical Education.

College LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
College of Phys. and Surgs., Chicago	(1907)	Illinois
Northwestern University	(1912)	Illinois

Omaha Medical College	(1896)	Nebraska

Book Notices

DIRECTIONS FOR A PRACTICAL COURSE IN CHEMICAL PHYSIOLOGY. By W. Cramer, Ph.D., D.Sc. Second Edition. Paper. Price, $1 net. Pp. 102. New York: Longmans, Green & Co., 1915.

This is one of the best guides for a general course in chemical physiology which we have seen. It is intended for the use of the medical student, and has just enough material to enable the worker to grasp the fundamental facts of physiologic chemistry, which are of such importance in the proper understanding of the clinical phenomena. The subject-matter is divided into three parts. Part I deals with animal and vegetable tissues and fluids; Part II treats of digestion, and Part III covers, in a general way, normal and pathologic metabolism. No attempt is made to present the subject in an exhaustive way, as this is necessary only for the specialist, for whom the book is not intended. The text, which is limited to experiments and deductions from these experiments, is presented in a clear and instructive manner. This work is recommended both to the teacher who may wish a brief and practical guide for his students, and to the worker who may desire to familiarize himself with the basic principles of chemical physiology.

PYELOGRAPHY (PYELO-URETEROGRAPHY). A Study of the Normal and Pathologic Anatomy of the Renal Pelvis and Ureter. By William F. Braasch, M.D. Cloth. Price, $5 net. Pp. 323, with 296 illustrations. Philadelphia: W. B. Saunders Company, 1915.

This is the first systematic presentation in any language of a method of diagnosis of kidney and ureteral affections, to which Voelker first called attention ten years ago. The author deplores the unjust condemnation of the method because of the deaths following its employment in a few cases. The majority of these ill effects were due to the use of too much force in injecting the solutions into the upper urinary tract. The book is based on the experience of the author in 2,000 cases, and the absence of any complication in this large number of pyelograms is the strongest argument for the gravity method which he employs. The numerous excellent roentgenograms show that pyelography is an almost indispensable diagnostic aid in renal and ureteral lesions. A careful study of the book is recommended to those interested in urologic as well as in general abdominal conditions.

EVOLUTION AND DISEASE. By J. T. C. Nash, Captain, R. A. M. C., T. F., S. S. Cloth. Price, $1.40 net. Pp. 73. New York: William Wood & Co., 1915.

This book consists of the Chadwick Public Lectures for 1913. The author traces in simple language the growth of our modern knowledge regarding the spread of disease, and shows the remedy in public education.

MISSOURI STATE MEDICAL ASSOCIATION

Fifty-Eighth Annual Meeting, held at St. Joseph, May 10-12, 1915

The President, DR. H. C. SHUTTEE, in the Chair

Pneumonia Treated with Rosenow and Hektoen's Antigen

DR. OLA PUTMAN, Marceline: Sixteen patients received the treatment without a fatality. The average time of crisis from the onset was four and one-quarter days.

DISCUSSION

DR. C. L. WOOLSEY, St. Joseph: I recently treated a patient, aged 62, who had developed the disease two days before he called for the doctor. His symptoms, therefore, were quite grave, including a bad mitral lesion. I gave him sensitized pneumococci, four injections, the last two containing 500 million germs. He made a speedy recovery.

Essential Hemorrhage from the Uterus

DR. C. H. WALLACE, St. Joseph: In essential hemorrhage from the uterus, the flow may occur without physical signs and symptoms, except the bleeding. This flow is never intramenstrual, generally is most excessive at the menstrual epoch, and may run from one period into another. The uterus may be slightly larger than normal, but perfectly mobile and with no other physical signs of disease. It occurs in the young or middle aged. The condition seems to be allied to uterine fibrosis. The hemorrhage may extend over a period of several years, the patient's general health being impaired from loss of blood.

DISCUSSION

DR. CARYL POTTER, St. Joseph: I do not believe in the conception of essential hemorrhage. There are several constitutional causes of hemorrhage. I should hesitate long before performing hysterectomy on a patient under 35 or before the menopause.

DR. JOHN J. SHELDON, Kansas City: Hysterectomy may be the only means of relief, but it is a great injury to the patient if done unnecessarily. The number of cases, however, demanding this extreme measure is exceedingly small.

DR. C. H. WALLACE, St. Joseph: In all my cases the ovary was left. Hysterectomy should be resorted to only after every other measure of relief has failed.

Renal Tuberculosis

DR. JAMES P. HENDERSON, Kansas City: Postmortem statistics show that from 50 to 60 per cent. of the cases are bilateral. It is of great importance to know whether one or both kidneys are involved and with what degree of destruction. Early tuberculosis affects but one kidney in from 90 to 95 per cent. of cases. It is my opinion that in cases of uremic anuria or acute suppression following surgical operation on one kidney, the other is found tuberculous in from 25 to 30 per cent., and that the destruction of the kidney is either primary or secondary in 95 per cent. of cases, and is secondary to tuberculosis elsewhere in the body. Tuberculosis of the bladder and ureter occurs in from 10 to 20 per cent., and is always secondary. In the acute miliary type there is no symptom to make the physician suspect the tuberculosis, all symptoms pointing to the systemic affection. In the caseating form there may be only constitutional symptoms, no local ones.

DISCUSSION

DR. E. G. MARK, Kansas City: No urine should be taken for diagnosis or accepted for that purpose except urine withdrawn by the catheter.

Dr. J. I. Byrne, St. Joseph: If persistent irritability of the bladder, frequent diurnal and nocturnal urination which does not respond to treatment, general systemic decline, blood pressure below normal, pus or blood in the urine, exists, you have reason to suspect renal tuberculosis.

Dr. J. P. Henderson, Kansas City: The majority of general practitioners can make the diagnosis without difficulty, but they fail in the treatment. Too often the bladder is held responsible, and treatment is given for a long period until the patient is completely "washed out."

Dr. C. R. Burford, St. Louis: Every general practitioner should be able to diagnose renal tuberculosis. There are two points to bear in mind: First, never examine voided urine for tubercle bacilli. Second, the initial complaint of the patient generally is of bladder irritability and lessened capacity of the bladder.

Unilateral Renal Hematuria

Dr. C. M. Nicholson, St. Louis, gave a description of the causes, varieties and pathology of renal hematuria with report of cases and the results of treatment.

DISCUSSION

Dr. W. J. Frick, Kansas City: With the various methods at our command, I believe we can usually make out the cause of this condition. The cystoscope is probably the most important of all the diagnostic methods we have, as it will show which kidney is bleeding and at the time tell us the condition of the other kidney. Next in importance is the Roentgen ray, by which we can ascertain whether the cause of the bleeding is a stone, which is the common cause for renal hemorrhage, or whether there is a tumor present, and sometimes we can obtain an idea of what kind of tumor it is if present. In tuberculosis of the kidney, the Roentgen ray may show caseation. Other methods are the microscopic examination of the urine and ureteral examination. Many cases present no symptoms except the hemorrhage, and these make up the so-called cases of essential hematuria, the diagnosis of which is made only by exploratory operation.

Dr. L. T. Dunaway, Eldorado Springs: I had a case of renal hematuria with which I worked for eighteen months. Finally I put the patient on nitric acid, 3 drops, three times a day, and in about four weeks she was well. Another woman had suffered for fourteen months, and was weak and anemic. Then she saw a boy fall from a table and was severely shocked. From that day on the hemorrhage ceased.

Dr. L. F. Body, St. Joseph: About twelve years ago, Steinwerk first discovered that renal hematuria was sometimes due to varix in the veins and papillae of the kidney. He curetted the bleeding points, and this was followed by relief of the condition. Others have made similar cures. Renal varix, however, is not the only cause of the trouble. Other pathologic conditions give rise to hemorrhage.

Dr. Jacob Geiger, St. Joseph: In the last few weeks I have operated in three cases which had been treated medically by competent physicians. I exposed the kidneys, but careful examination failed to disclose any pathologic condition. After splitting the kidneys and suturing with catgut, I replaced the organs, and all the patients are apparently well.

Dr. E. G. Mark, Kansas City: I have wondered whether the angioneurotic kidney is not responsible for the so-called essential hematuria. To have hemorrhage you must have some pathologic condition; yet we are sometimes confronted by cases in which we operate when no pathologic condition was found beforehand and no abnormal condition discovered later in the laboratory. The operation of splitting the kidney is unquestionably beneficial.

Dr. J. E. Dewey, Springfield: A man of 56 had been suffering from hematuria for three years. I was unable to find anything the matter with the kidney, so I removed it. Later searching showed a small concretion in one of the papillae which it would have been impossible for the man in his anemic condition to throw off. The second case was in a young man, an epileptic, who had been bleeding for fifteen months. We could find no lesion, either before or after nephrectomy. Perhaps these cases would come under the head of angioneurotic kidney.

Dr. C. M. Nicholson, St. Louis: Since in the majority of cases the symptom, whether or not we know the pathologic condition, is what we are treating, if it can be overcome by simply bisecting the kidney, this is better than to perform nephrectomy.

Factors of Safety in Goiter Operations

Dr. Vilray P. Blair, St. Louis: Refraining from radical operation during the height of crises, in the presence of grave degeneration, or functional disturbances of vital organs, is the most important working rule. A more potent factor, but rarely within the surgeon's control, would be to do necessary radical operations at an earlier period of the disease, before goiters reach the intensely toxic stage, before they cause degenerative changes in vital organs, and before they have become fixed in positions that render their removal excessively difficult and dangerous. Except in the presence of imminently grave obstruction, patients with simple goiters who are in poor condition should be nursed along until they are acceptable risks before thyroidectomy is undertaken. *Preliminary ligation of thyroid vessels is ordinarily the most* effective way of reducing the toxicity of exophthalmic goiters, and the postoperative behavior of the patient serves as a reliable indication as to how well a thyroidectomy would be tolerated. The avoidance of antiseptics and general anesthetics also reduces the liability of postoperative intoxication. Preservation of the integrity of important structures, the recurrent laryngeal nerves, parathyroids, the trachea and pharynx, is best assured by careful hemostasis during operation, the extraglandular ligation of the thyroid arteries and the preservation of the posterior capsule of the gland.

DISCUSSION

Dr. W. T. Coughlin, St. Louis: We do not have the selection of cases in our hands. Usually the patient is sent to us with the expectation that we will operate. If the profession were educated to the point where patients would be sent to the surgeon as soon as response to medical treatment fails, the surgeon's work in selected cases would be greatly simplified. If the goiter has developed very rapidly, it is just as well to let it alone. The most dangerous cases are the rapidly growing exophthalmic type. If the patient fails to benefit by rest in bed, surgery should not be undertaken.

Dr. V. P. Blair, St. Louis: There is one class of exophthalmic goiter which comes to the surgeon in which he will avoid operation if he regards the individual's good, unless forced to take the risk, that is, the goiter which has gradually led up to crisis, which has existed for a long time and shows evidence of degeneration, especially if mental symptoms are developing. Very interesting at present is the question of operating in those cases in which there is a suspicion of involvement of other ductless glands. Our present position is that, given a case of exophthalmic goiter, regardless of what other ductless glands may be involved, the removal of thyroid tissue will help the patient.

Dr. Roland Hill, St. Louis: One point which ought to be emphasized is that goiters giving rise to nervous symptoms, especially in women over 25, should be seen by the surgeon before marked degeneration occurs.

Gastro-Enterostomy

Dr. Herman E. Pearse, Kansas City: The average length of time that patients endure dyspepsia and various stomach symptoms due to gastric and duodenal ulcer before coming to the surgeon for cure by gastro-enterostomy is fifteen years. The symptoms that bring patients to successful operative cure are pain, loss of weight, vomiting and hemorrhage.

DISCUSSION

Dr. Willard Bartlett, St. Louis: We do not operate for ulcer. We do not know what causes an ulcer, nor does any surgical operation cure the operation per se, an ulcer always being a secondary condition. We operate for certain complications of ulcer, and obstruction is the one which most commonly brings the patient to operation. Perforation practically always demands immediate operation; we operate for small repeated hemorrhages which gradually deplete the patient; we operate for cancer on an ulcer basis and for "medical failures," although not using that term in any sense as a criticism, because from the very nature of the facts, many medical treatments are bound to fail. I do not believe that more than two fifths of all ulcers are surgical; three fifths are greatly benefited if not actually cured by such methods as are used by Sippy and others. Five forms of operation are applicable to ulcer, according to the case. Certain operators resect the ulcer-bearing area. Certain others resort to blocking the stomach at some point so that food cannot go over the ulcer area, and a drainage operation is done. Then there is excision of the ulcer, the fourth method, pyloroplasty, which is seldom used, and the fifth method, gastro-enterostomy, which is by far the most frequently used and the most useful of all operations for this condition.

A Question in Dealing with Abdominal Adhesions

Dr. Frank G. Nifong, Columbia: The formation of abdominal adhesions is one of Nature's methods of limiting the extension of the infection. The observation of adhesions in animals indicates that Nature provides those most exposed to infection by habits and environment with the greatest ability to form adhesions. Resistance to peritoneal infection seems to be in direct proportion to the animals's power to form adhesions. The kind of infection producing the inflammation has something to do with the readiness by which adhesions are formed. Late postoperative shock, so-called "secondary shock" is not truly shock, but is due to the overwhelming of the nerve centers by the sudden turning loose of a large dose of protein poison. Theory is not incompatible with Crile's kinetic theory, but the application of the principles of anoci-association is impracticable. Breaking down old adhesions, breastworks in the presence of leukocytosis, or active battle in war analogy, would seem to be treasonable. What is needed from a surgical standpoint is some index to the patient's resistance and the amount of operative procedure permissible.

DISCUSSION

Dr. H. E. Pearse, Kansas City: The presence of the retained shock is correctly attributed by Dr. Nifong to the blow of extensive internal dissection. But when the heart is struggling under a load of infection, it seems to me a poor plan to add 30 or 40 ounces to the circulation by intravenous transfusion. It is desirable to dilute the blood and dilute the toxemia. I have seen two patients die very promptly from this method of treatment. The water should be placed under the skin where Nature can make use of it if she wants to take it up, but it should not be put into the circulation. The one thing that has pulled these patients through for me whenever everything else failed is atropin.

Dr. W. T. Coughlin, St. Louis: I believe that delayed shock always indicates latent hemorrhage. The patient who dies from shock never reacts after the primary operation. Epinephrin is a very dangerous drug and should be used, if used at all, with extreme caution.

Tumors of the Carotid Body

Dr. C. W. Russell, Springfield, cited a case of ten years' standing, with a brief review of the anatomy, physiology and embryologic features so far as they have been investigated.

DISCUSSION

Dr. J. F. Binnie, Kansas City: About twenty years ago I operated for a tumor that I had diagnosed lymphangioma on the right side of the neck. In the course of the operation I changed my mind, and told the students present that I thought it was one of those cases then recently described in English literature as a potatolike tumor of the neck which had crystallized into tumors of the carotid. If I remember rightly, I dissected the tumor out without ligating the carotid vessels. The diagnosis of tumor of the carotid body was confirmed by Dr. Frank Hall. The subsequent history of the case was lost in the chaos which surrounded all city hospital records in Kansas City at that time.

Dr. C. W. Russell, Springfield: About two years following the removal of the tumor, there appeared on the opposite side of the neck a small, freely movable tumor, which was properly located and which I removed. It proved to be a hypertrophy of one of the lymph nodes.

ASSOCIATION OF AMERICAN PHYSICIANS

Thirtieth Annual Meeting, held at Washington, D. C., May 11-13, 1915

(Continued from page 2091)

A Method of Determining Total Plasma and Blood Volume

Drs. L. G. Rowntree, N. Keith, and J. T. Geraghty, Baltimore: The method consists of injecting into a vein a given quantity of nontoxic, nondialysable red dye; in three and six minutes, specimens of blood are taken and the degree of dilution of the dye determined. A standard solution is prepared by securing some blood before the dye is injected, and diluting an amount of dye equal to the dose to 4 per cent. of the body weight, using for the diluent 1 part serum and 3 parts salt solution. When the blood is taken after the injection of the dye, the serum is separated, diluted and compared with the standard solution: from this point the calculation is easy. The loss of the dye from the human circulation has been found to be only from 1 to 2 per cent. The dye cannot be found in the tissues, and it is not believed that it goes into the blood cells, either red or white. The average figures in normal individuals indicate that the blood volume should be 85 c.c. per kilogram, or about one twelfth the body weight. In essential hypertension and in diabetes, the blood volume has been found to be normal. In pregnancy there is a large increase in the blood mass which does not disappear until from seven to ten days after delivery. This would seem to be a physiologic preparation for hemorrhage.

Simple Method of Determining Variations in the H Ion Concentration in the Blood

Drs. L. G. Rowntree, McKim Marriott and R. L. Levy, Baltimore: The method consists of adding an indicator (phenolsulphonephthalein) to the dialysate of blood serum and comparing with a solution of known H ion concentration. The normal figures for H ion concentration are from 7.6 to 7.8. Many cases have been studied, among them twenty cases of acidosis, all of which have shown a concentration toward the acid side, as low as 7.0. In experimental acidosis, the readings went as low as 6.7, at which point the animals died. In alkalosis, the readings may go up to 8.0 or 8.1, when the animal dies. By this method the buffer values of the blood may be determined, and in acidosis the buffer values are very low. It is an easy method to study both acidosis and alkalosis from the blood side.

Case of Severe Anemia with Leg Ulcer and Remarkable Blood Findings

Drs. Jerome E. Cook, Jerome Meyer and George Dock, St. Louis: The case is one of severe anemia occurring in a young mulatto girl. There is a complication of recurring, indolent, leg ulcers. The red cells show the greatest degree of variation both in size and shape, giving the appearance as if many of the cells had been broken into fragments; but the most frequent abnormal type is a much elongated, curled red cell often more or less sickle shaped. Among the white cells an eosinophilia of varying and sometimes intense degree is the most marked feature. The other children in the family (two), are dead; both suffered from severe anemia. Two similar cases are recorded in the literature; both cases were in mulattos and both had a chronic type of leg ulcer.

Unusual Condition of the Blood in Primary Pernicious Anemia

Dr. N. E. Brill, New York: A woman, aged 43, mother of five children, nonsyphilitic, presented all the classical signs of a primary pernicious anemia, which began one year ago, insidiously, with gradually increasing sense of fatigue and later weakness with disturbed gastric symptoms, as vomiting for three weeks, and eructations of gas. Six weeks before coming under observation, weakness became extreme, and the skin pale and light yellow; visual power markedly diminished; cardiac palpitation, tinnitus aurium and vertigo were complained of; there had been no bleeding from the mucous membranes or into the skin. Six pounds were lost in weight during the year. Physical examination revealed a yellow skin, a slightly enlarged liver, a relatively larger spleen which could be felt over 3 c.c. below the costal border; tender tibiae and sternum, and a blood picture of high color-index (1.5) and the associated conditions of the cells indicating the presence of an anemia gravis. A transfusion of blood was done, followed in thirty-six hours by a splenectomy; following this an absence of the usual bone-marrow reaction was noted, though there was a gradual physical improvement in the patient, to the extent that she could walk again without the distress which had previously existed. In five weeks after her discharge from the hospital, there was a furibund recurrence in her symptoms which brought her back to the hospital in a worse condition than at any previous time. The blood then showed a tremendous loss of red cells, an increased activation of the leukoblastic and the erythroblastic tissues of the bone marrow, the circulating blood containing early myelocytic forms of cells, "myeloblasts or myelogones," of which a large number were phagocytic, containing one or more red cells in their cytoplasm, and a myelocytosis of 21 per cent., all accompanied by a hemoglobinemia and hemoglobinuria with the final blood picture of an acute myeloid leukanemia (von Leube) immediately before death. No necropsy could be obtained. The question arises, What relationship, if any, had the splenectomy on this unusual activation of the bone marrow?

Metabolism Studies Before and After Splenectomy in Congenital Hemolytic Jaundice

Drs. Samuel Goldschmidt, O. H. Perry Pepper and R. M. Pearce, Philadelphia: The patient had had a severe anemia from birth with the later usual history. Metabolism studies were made both before and after splenectomy. The blood picture after operation showed marked improvement. In general, the studies indicated a tendency to lose nitrogen before splenectomy and to retain nitrogen afterward; the operation seemed to restore the capacity for nitrogen utilization. There was a high elimination of uric acid before splenectomy, with a drop of 47 per cent. in uric acid output after the operation. The iron elimination before splenectomy was 50 per cent. above the intake; after operation the iron elimination was greatly reduced. There was also a reduction of 90 per cent. in the urobilin elimination in the feces. These figures seem to support the evidence of the real benefit of the operation. Removal of the spleen seems to remove the toxic agent or the source of it, and in addition the hemolytic agent is removed as well.

Plasmaphaeresis

Drs. J. J. Abel, B. B. Turner, E. K. Marshall, Jr., and P. D. Lamson, Baltimore: Among the many points of view from which one may study the minute structures of the blood, the relation of cells to plasma led to experiments which consist of the removal of the plasma of withdrawn blood and the return of the cells to the circulation, a process to which has been given the name plasmaphaeresis. The method is as follows: An animal is bled very freely, almost to fatal exsanguination, the blood caught in a solution of herudin to prevent coagulation, diluted to double its volume with Locke's solution, centrifugalized and the supernatant plasma discarded. The cells are now diluted to the original bulk of blood with Locke's solution, and restored to the circulation of the animal. This may be done repeatedly from time to time without injury to the animal. Blood pressure estimations showed that the low pressure of the exsanguinated state was well restored on the return of the fluid to the vessels. It was also found that leech extract is not toxic, at least to the extent in which we use it. But since the war, the supply of leeches has been interrupted and a manufactured herudin has been tried; this product is very toxic, quantities as small as 10 mg. being sufficient to kill animals with symptoms of great shock.

Preservation in Vitro of Living Erythrocytes

Drs. Peyton Rous and J. R. Turner, New York: There are several practical purposes involved in attempts to preserve intact mammalian red blood cells: for culture materials in the cultivation of plasmodia; for readily available indirect transfusion material, etc. Washed cells were first used, but were found to disintegrate very early. The addition of citrated plasma prevents this injury. Gelatin, in the proportion of 0.125 per cent. in Ringer's or salt solution will also protect the cells for a long time. Cells were tested by shaking to compare their fragility when thus treated with their fragility to hypotonic salt solution: there was no relation between the degrees of fragility, though bloods differ in their behavior in this regard. Human blood cells can be washed without injury. Cells are protected but not preserved by gelatin; the addition of glucose or saccharose, however, to gelatin Ringer's solution will preserve the cells for a long time. Cells that have been kept several weeks take up and surrender oxygen normally, do not clump or show morphologic change, and behave normally in the Wassermann reaction. Rabbits were exsanguinated, and preserved blood used to supplant that withdrawn; the animals were fully restored and behaved normally after the operation. Many tests corroborated this experience. Rabbit blood can be kept alive at least two weeks. Human blood can be kept for several weeks in dextrose-gelatin solution. Effete blood cells when introduced into the circulation can take up and give off hemoglobin, but they quickly disappear from the circulation; but when the animals are treated by the introduction of blood preserved in the manner described, no changes can be found afterward, even in the spleen.

Clinical Studies in Blood Transfusion

Drs. E. Libman and R. Ottenberg, New York: In simple hemorrhage, the results of transfusion were uniformly good, especially in hemorrhage of gastric and duodenal ulcer. Transfusions made during the progress of the hemorrhage acted equally well as when made after the accident, and seemed to encourage spontaneous arrest of the effusion. In six cases of dysentery, transfusion was followed by marked improvement. In seven cases of typhoid hemorrhage, nine transfusions were done with two recoveries. Transfusion is useful in operative work, both before and after operation; but it is of no help in surgical shock. In purpura hemorrhagica, transfusion was done twelve times in nine cases; six patients recovered, the two deaths being in cases occurring shortly after pregnancy. In this disease, transfusion appears to have a direct curative value. For hemophiliacs, a donor should be picked in advance for possible needs. For prophylactic purposes, a small transfusion every few months may be useful. Transfusion is much more helpful than the injection of serum. For the treatment of postoperative hemorrhage in obstructive jaundice, transfusion was not of material benefit. The suggestion was made that in this condition there should be a preliminary bleeding with a large transfusion from several donors. In pernicious anemia and leukemia, the results were not uniformly good. In twenty-five cases of pernicious anemia, fourteen showed for a time progressive improvement; eight of these patients are alive at the present time, but they all present evidences of blood trouble. In eleven cases, transfusion was of no avail; two cases were also splenectomized without improvement. In one case, there were four transfusions, followed later by splenectomy; a remission then took place. Transfusion does more than anything else to abate the blood symptoms. It is important to try several donors when no improvement follows one or more transfusions from a single donor.

The effect of transfusion on the symptoms of pernicious anemia may be summarized thus: The appetite improves, the mental symptoms grow better, the glossitis clears up, and the blood picture improves; but the spinal cord symptoms do not improve. There is fever in 50 per cent. of the cases;

some become afebrile after transfusion. The fever may be due to toxic causes or to the anemia. In this disease, splenectomy is advisable; if no remission occurs after the operation, then transfusion should be done; or if remission does not follow transfusion, then splenectomy should be resorted to. We may thus determine the relative values of the two methods of treatment. In leukemia, there was some improvement following transfusion in a number of cases; but it was not lasting. In acute infections, transfusion has no very large field of application. Patients may be helped along by it at times, but the best results are to be had in long-continued subacute infections. In endocarditis with retention of infection, transfusion does good only to the extent of prolonging life for a time. The Unger method of direct transfusion and the Weil citrate indirect method are the best, and will supersede all others.

Discussion on Blood and Blood Diseases

Dr. R. C. Cabot, Boston: In six cases of pernicious anemia, splenectomy has been done in the past four months. No marked improvement could be noted in the first two or three weeks after splenectomy; then there was a rapid rise in the cell count, more rapid than that which may be noted in a spontaneous remission or after treatment by transfusion or salvarsan. All of the cases have gone above 4,000,000 in the cell count. Four out of the six patients are now at work, whereas before the operation they were entirely helpless. The blood still shows very definite changes.

Dr. Joseph L. Miller, Chicago: Removal of the spleen does not remove the hemolytic agent; it seems to stimulate resistance of the cells and the bone marrow, so that the blood recovers somewhat in spite of the hemolytic agent. I recall a case in which there were progressively increasing spinal cord lesions after splenectomy, thus further indicating the retention of the hemolytic agent.

Dr. R. Weil, New York: Concerning the toxicity of sodium citrate, I used enough to keep blood fluid and in some cases to preserve such blood as long as two weeks, and then to reintroduce this blood into the circulation of animals without toxic effect. In man, 5 gm. of the citrate may be injected without producing any symptoms. The use of sodium citrate and of citrated serum has been found to have the curious effect not of increasing the coagulation time but of decreasing it. This observation may play an important rôle in the treatment of hemorrhagic diseases.

Dr. Theodore C. Janeway, Baltimore: My work on the arteries has shown such a lethal effect of sodium citrate on the arterial walls that it suggests caution in the use of citrated blood. Perhaps the citrate used in a transfusion is too dilute to do any harm. The results of transfusion in cases of pernicious anemia coming under my observation have been even better than those reported by Dr. Libman.

Dr. J. J. Abel, Baltimore: I have observed relaxation of the intestinal strip in citrate solution, but this is not comparable to work in vivo.

Dr. R. Weil, New York: I have injected as much as 1,400 c.c. citrated blood without producing symptoms, and I have given 5 gm. sodium citrate in water a number of times without untoward effect.

Dr. Peyton Rous, New York: It is possible to use kept corpuscles without citrate by sedimenting and pipeting off the plasma. In using preserved blood, it must be remembered that dextrose delays clotting.

Dr. W. S. Thayer, Baltimore: I have a patient who has a grave secondary anemia with a leukocytosis of 20,000. There is an increased resistance to hypotonic salt solution and a great increase of vitally staining cells.

Dr. E. Libman, New York: Dr. Lewis has been working with herudin and has observed the same toxicity of the manufactured article to which Dr. Abel has called attention. I would not be in favor of separating cells from plasma in transfusion work as suggested by Dr. Rous. I have seen one case in which mild diarrhea followed the transfusion of citrated blood. The symptom was trifling and its significance doubtful.

Dr. N. E. Brill, New York: Metabolism studies in my case of pernicious anemia showed no difference in iron elimination before and after splenectomy. With better protection of cells and greater production after splenectomy, it stands to reason that there should be a retention of blood. Lecithin is known to protect blood cells, but in my case there was no increase of lipoid in the blood after splenectomy.

Treatment of Tetanus by Antitoxin Given Intraspinally

Dr. Matthias Nicoll, Jr., New York: Experiments were made to ascertain the value of intrathecal administration of antitoxin. Guinea-pigs were given twice the minimum lethal dose of tetanus toxin; they died in three days. Pigs treated thus were given antitoxin by injection into the heart cavity; they died in from five to eight days. Tetanic pigs treated by injecting antitoxin into the sciatic nerves did no better. But pigs treated by injecting one twentieth the dose of antitoxin used in the other animals into the spinal canal recovered. Several pigs were allowed to grow so tetanic that they were twisted into grotesque shapes; out of six treated by intraspinal injections of antitoxin, three recovered. Twenty human patients were treated with intrathecal injections of antitoxin, and sixteen out of the twenty recovered. The method of treatment recommended is to give from 3,000 to 5,000 units into the spinal canal, diluting the serum to from 10 to 20 c.c. to make it thin and easily diffusible; posture is not required to assist diffusion. In addition, 10,000 units should be given intravenously. The intraspinal injection should be repeated in twenty-four hours and if necessary, the intravenous injection should be repeated also. By this method, the mortality of tetanus has been reduced to 20 per cent.

(To be continued)

AMERICAN PEDIATRIC SOCIETY

Twenty-Seventh Annual Meeting, held at Lakewood, N. J., May 24-26, 1915

(Concluded from page 2094)

Allergy to Common Foods

Dr. Oscar M. Schloss, New York: A number of cases of eczema and bronchial asthma prove to be due to food allergy. A satisfactory result can be obtained in some of these cases, but not in all, because there is a lack of proper substitute foods, and it is difficult to secure the reaction in all cases. The guinea-pigs used in these experiments were divided into two groups, one of which was egg fed. After thirty-five days, they were found anaphylactic. Of the others, which were fed on egg for several months, none had developed immunity. The treatment should consist either in the administration of gradually increasing amounts of the toxic protein, or in eliminating the offending protein from the diet.

DISCUSSION

Dr. John Howland, Baltimore: These children are sensitive to so many proteins that it is hard to give them a food on which they can be nourished. The subcutaneous test is more sensitive than the cutaneous, but more difficult to interpret. This differs somewhat from anaphylactic shock, in that it is impossible to produce passive sensitization in animals or to obtain precipitins from their blood.

Dr. Fritz B. Talbot, Boston: The longest absolute cure I have had is three years. In about 60 per cent. of a large number of cases of asthma that I have seen recently, I have found a positive skin test to some food. Egg was the most common offending article.

Dr. S. McC. Hamill, Philadelphia: In some investigations which I have been making, I have been struck with the number of times I have obtained the reaction in children with no very definite manifestation of anaphylaxis, but with gastro-intestinal trouble accompanied with recurrent attacks of diarrhea.

Dr. Royal S. Haynes, New York: I have treated several cases of asthma in which the child was sensitive to egg, and in which it was also necessary to limit the amount of chicken. If the child ate a little egg or chicken, but not sufficient to develop asthma, it would get a return of eczema.

Dr. Rowland G. Freeman, New York: Many children have been injured by the assumption that they have an idiosyncrasy to cow's milk. I have found none that I could not give it to, if I began with a small amount and gradually increased it to a normal quantity.

Dr. Isaac A. Abt, Chicago: While some children take care of these foods badly, others can take them without any toxic response; and the question is whether the result is due to an abnormality in the food or in the child. If in the latter, have we any means of classifying this idiosyncrasy on the part of the children?

Adaptation of an Artificial Food to Human Milk

Drs. H. J. Gerstenberger, H. D. Haskins, H. H. McGregor and H. O. Ruh, Cleveland: There is a means of eliminating the low volatile fatty acids, for the homogenizer makes it possible to mix this fat with other constituents of the food in the form in which it exists in breast milk, and also to add any other thing that further investigation may develop, thus affording a practical method of getting much closer to securing for the great bulk of children in the cities a food which needs no dilution and can be fed to a young infant, as well as to an older one. The bacterial content is very low. The food is cheap, and will probably prove of great value to the general practitioner.

Homogenized Olive Oil-Fat-Free Milk Mixtures in Cases of Difficult Feeding

Dr. Maynard Ladd, Boston: Foreign milk usually contains a much higher percentage of fat than foods given in its place. This fact led to experimentation with other foods. By homogenizing, we are able, in cases of intolerance to cow's fat, to combine these foods with skimmed milk and produce a perfect emulsion. We can combine chemically pure casein with pure oils and pure sugars. My experiments thus far justify me in believing that in this way a food can be obtained which can be given with great improvement to the health of the patients. Olive oil combined with fat-free milk might be of great value, for olive oil costs only about a fourth as much as cream. I have had success with this method of feeding in one or two very difficult cases, but my experience has not yet been sufficient to warrant me in drawing conclusions.

DISCUSSION

Dr. B. Raymond Hoobler, New York: There are two types of fats: those which come from glandular tissue and those which are not glandular in type. Animals are not sufficiently or properly nourished on the latter kind of fats, but when glandular fats are added to their food, nutrition takes place. An increase in weight is not sufficient evidence of true nutrition; the animals must be able to produce normal offspring. Animals fed on nonglandular fat are unable to do this. We should inquire whether the foods suggested are capable of fulfilling this standard of nourishment.

Composition of Woman's Milk

Drs. L. Emmett Holt, Angelia Courtney and Helen M. Fales, New York: After the first month there are no practical differences in the composition of the milk until the end period. The fat is highest in the transition period. In the late period, it was as high as in the mature period, except in one case. In only one case was the sugar less than 7 per cent., and in over half the cases it was over 8 per cent. It showed a diminution in quantity up to the late period. The protein did not differ much from the amount found in the early period. The milk differed but little in composition at the various ages. The total ash is practically the same in all. The ratio between the protein and the ash in human milk is practically the same as in cow's milk in the mature period, 1:5. In cow's milk, in ordinary dilutions, we are giving more mineral than the child really needs.

DISCUSSION

Dr. Henry J. Gerstenberger, Cleveland: What were the iron determinations?

Dr. Thomas S. Southworth, New York: One of the interesting things is the high fat in the transition period. The bad effects of this high fat content of the mother's milk at this stage can be overcome by diluting it with some alkaline solution. The fact that the fat is normally high at this time and then begins to decrease shows that Nature comes to our aid by lowering the amount of fat.

Dr. L. Emmett Holt, New York: The percentage of iron found by other observers is 1.7 mg. in 1,000 c.c. of milk.

Sugar in Infant Feeding

Drs. Charles H. Dunn, Boston, and **Langley Porter**, San Francisco: Eighteen patients were observed, 108 samples of urine tested, and 235 tests made. Twelve of the eighteen cases showed reducing bodies on some tests. Eight showed a loss in reducing power after shaking the picric acid. The majority were difficult feeding cases. None showed marked intolerance to any of the food elements. The effect of increased sugar on the weight of the babies was surprising. They gained rapidly at first, but less rapidly after sugar intolerance developed. It is our belief that the idea of sugar intoxication has been so exaggerated as to keep us from trying the effect of large amounts of carbohydrates for babies who show an inability to take a sufficient amount of food. Some children have been much benefited by pushing the amount of sugar temporarily above the ordinary limits.

DISCUSSION

Dr. Oscar M. Schloss, New York: Some results that we obtained about a year ago did not accord with those cited. In many instances we found that the infant's urine would reduce copper, and occasionally bismuth. In a number of instances we were able to determine that the reducing substance was sugar. This sugar, however, was not lactose. It was a monosaccharid, sometimes dextrose and sometimes galactose.

Dr. Langley Porter, San Francisco: There is no necessary antagonism between these findings and those in our paper; these were cases merely of disturbance, and not of intoxication. The interesting thing was the presence of reducing bodies other than sugar in such a large proportion of the urines of infants.

Dr. I. A. Abt, Chicago: The idea of Finkelstein and his school is that sugar or any other food element finds its way into the circulation because there is a damaged intestinal wall. It is not damaged by the sugar or any other food, but by bacterial action or the toxic product resulting from bacterial action. Food intolerance merely means that the food breaks through the intestinal barrier.

Dr. L. Emmett Holt, New York: What about the permanence of the gain in weight in these children? A child can have intolerance for a small amount of sugar and tolerance for a large amount. We have seen so many symptoms in children getting small amounts that we have hesitated to give a larger amount of sugar.

Dr. Henry Koplik, New York: There is a limitation to the amount of sugar we can administer to these children. If you persist in administering this large amount, the children gain for a while, then stand still, and finally lose.

Dr. Henry J. Gerstenberger, Cleveland: A high protein content will allow of a much higher percentage of sugar, and a low one most likely limits the amount.

Dr. DeWitt H. Sherman, Buffalo: Some studies made by us seem to show that lactose stimulates motor function in the stomach more than either cane sugar or malt sugar. That, however, is probably not true, for the reason that the secretion following the ingestion of lactose was no greater than after the other two. We concluded that cane sugar stimulates the gastric secretion a little more than lactose, but that dextromaltose stimulates the secretion twice as much as lactose.

Dr. J. P. Crozer Griffith, Philadelphia: Last winter I tried feeding infants with foods rich in carbohydrates, and found they did very well, being able to tolerate from 10 to 13 per cent. perfectly.

Dr. Charles H. Dunn, Boston: The problem we are studying is the possible damage produced by sugar. In this series of cases, the gain in weight was maintained, but the sugar was immediately cut down when symptoms of intolerance developed. I believe that the chief cause of those severe cases in which fat cannot be taken is prolonged overfeeding with sugar. The amount of protein given was 2.5 per cent. We found that many specimens of lactose contain gas bacillus spores and other things that tend to lead to trouble and make us draw wrong conclusions.

Indications for Treatment of Severe Diarrhea in Infancy

Drs. John Howland and W. McKim Marriott, Baltimore: We tested the alveolar air in infants, and found that the carbon dioxid tension in such cases is lower than in health, especially if dyspnea is present. This low tension is an evidence of acidosis. Giving alkalies in large quantities causes the carbon dioxid tension to rise and the dyspnea to disappear. Cathartics should not be given unless there is distention of the abdomen accompanied by fever. Opium should be administered in sufficient quantity to prevent more than two or three stools a day, and alkali (preferably sodium) given, with water, in sufficient quantity and often enough to cause the dyspnea to disappear and to overcome the diarrhea. The condition is not a food intoxication, but the absence of a substance necessary to life.

DISCUSSION

Dr. Henry Koplik, New York: Opium is a dangerous drug in these cases, sending the children into a deeper stage of intoxication. Why attempt to stop peristalsis? Diarrhea is a means by which Nature eliminates a certain amount of poison.

Dr. Oscar M. Schloss, New York: In some work which I did during the past year, I obtained results exactly comparable to those of Dr. Howland. In cases of severe intoxication and dyspnea, there was a marked lowering of the carbon dioxid in the blood.

Dr. Henry J. Gerstenberger, Cleveland: I should like to know the dose of alkali which Dr. Howland gives.

Dr. Charles G. Kerley, New York: Opium is one of the best drugs to use in intestinal diseases, but it must be used carefully. Drainage may be so excessive as to exhaust the patient.

Dr. I. A. Abt, Chicago: It is important to give these children the proper kind of food to prevent acidosis, as well as to administer alkali to correct this condition.

Dr. A. D. Blackader, Montreal: We can check peristalsis entirely with a large dose of opium, while, with a smaller one, we can check it just enough to give the digestive fluids a chance to work in the intestine. In cases of normal children, even when a cathartic is given, the stools contain much undigested food. Small doses of opium, repeated often enough to prevent this extreme waste, have never caused any disastrous results, in my experience.

Dr. Julius P. Sedgwick, Minneapolis: Study of the creatin-creatinin excretion in these cases of acidosis might aid in clearing up this problem.

Dr. John Lovett Morse, Boston: If there is something in the bowel that needs to come out, one should give a cathartic; but if everything doing harm is out, and the diarrhea is merely draining the tissues of water and salts, we do harm with a cathartic and good with opium. It is advisable to give alkalies before these severe symptoms develop.

Dr. Fritz B. Talbot, Boston: In studying a large number of new-born infants, we found that the respiratory quotient was very low on the second or third day of life. It was such a low respiratory quotient as we get with acidosis or diabetes. We have not, however, found acetone bodies in the urine.

Dr. John Howland, Baltimore: I dislike the term "acidosis," because it has been applied so loosely to a number of different diseases in which physiologic acidosis is not present. The fact that a small number of bodies of the acetone series can be found in the urine does not prove that acidosis is present. It is only when the protective mechanism of the body is called into play that we can speak of acidosis. If the infant's abdomen is distended, the intestines being full of putrefying substances, and the baby has high fever, opium should not be given. These children do not, however, come in that condition, but with a retracted abdomen, the intestines being empty. It is dangerous to let them have eight or ten large stools a day. I give a few drops of opium after each loose stool. It is surprising how much they can take without influencing their stupor in the slightest degree. We usually give 4 gm. of alkali at a time, subcutaneously, 5 or 6 gm. intravenously, and 3 or 4 gm. by mouth. I believe protein milk, rather concentrated, and in small amount, to be the best food for these patients. The appetite is almost always lost, and many infants vomit everything that is ingested.

Reducing Substance in Spinal Fluid

Drs. Oscar M. Schloss and Louis C. Schroeder, New York: The reducing substance in spinal fluid is a fermentable, dextrorotary sugar, probably dextrose. In infants free from meningeal disease, the spinal fluid sugar ranges from 0.05 to 0.134 per cent. Approximately the same figures would obtain in cases of meningismus. The spinal fluid sugar is normal. In epidemic cerebrospinal meningitis, and suppurative forms of meningitis, the sugar is greatly reduced or absent. A large proportion of the cases of tuberculous meningitis show a decrease in the sugar of the spinal fluid. An increase of sugar alone is of diagnostic importance in this disease. The reducing substance was not found decreased in cases of idiocy, cerebrospinal syphilis or anterior poliomyelitis.

DISCUSSION

Dr. Alfred Hand, Jr., Philadelphia: I have examined the spinal fluid in many cases, and have found the absence of sugar in suppurative meningitis, and its presence in practically every case of tuberculous meningitis. I have come to depend on this fact in making the differential diagnosis. I believe that the ferment produced by the polymorphonuclear leukocytes causes the disappearance of the sugar in epidemic and suppurative forms of meningitis.

Meningitis in the Newborn

Dr. Charles Herrman, New York: The infection may take place through the placental circulation, but this is probably rare. It may also occur, in cases of difficult labor, through premature respiration on the part of the infant, resulting in the swallowing or aspiration of contaminated amniotic fluid. Infection may likewise take place at birth, through an injury to the skull; or after birth, through the eyes, ears, nose, gastro-intestinal tract, umbilicus or genitalia. From the fact that the *Bacterium coli* is the most common causative agent in such cases, it seems probable that the infection takes place through contaminated water in the bathing tub.

DISCUSSION

Dr. Henry Koplik, New York: I have seen several cases of meningitis in the new-born. Babies are considered as new-born in hospitals up to the third month. Most cases are usually of streptococcic origin. One of the cases I saw was a colon meningitis; another was due to a bacillus similar to the typhoid.

Dr. L. E. LaFetra, New York: The symptoms of meningitis are not evident in these cases, the infants showing great depression or symptoms of sepsis. They do not have very high temperatures. Various organisms are found.

A Case of Amaurotic Family Idiocy in One of Twins

Dr. Charles Herrman, New York: Alcohol and syphilis have been considered factors in the etiology of this disease, but it is difficult to see how any condition in the mother could affect only one of twins. These children received breast milk for only two weeks, and it could hardly be considered to be toxic for only one child. The theory of arrest of development must also be given up, because the brain of the amaurotic infant is normal morphologically at birth and for some time afterward. Then there gradually occurs a degeneration of all the ganglion cells and loss of function. The tendency to degeneration must be born with the child and develop subsequently. Some endogenous factor comes in and affects these children, although it does not do so in one born without this weakness.

Macewen's Sign: Analysis of Anatomic Conditions which Enter Into the Production of this Sign; Its Value in Diagnosticating Changes in Intracranial Pressure

Dr. Herbert B. Wilcox, New York: A positive Macewen's sign exists when variation from the normal note is found. It consists in a relative change, rather than in a definite condition common to all diseased crania. The sign is better elicited by the stethoscope than by the unaided ear. Increased clearness of sound when percussion is made over the posterior portion of the skull, rather than near the stethoscope, is diagnostic. The sign uniformly accompanies conditions of increased intracranial tension, and is not found unless the causative factor exists. It is equally applicable to infants and to older children.

DISCUSSION

Dr. L. E. LaFetra, New York City: To me, the pitch of the sound seems of more value than its loudness. The pitch becomes higher as one approaches the bell of the stethoscope. I think the sign will prove of value in cases that are not meningitis, but meningismus, or some other type of spinal condition with increased spinal fluid.

Dr. Henry Koplik, New York: This is the most useful sign we have of beginning tuberculous meningitis, ordinary meningitis and serous meningitis due to otitis media. I find the greatest difficulty in applying the sign in the case of children who have had rickets. It is difficult in them to tell how much the sign is due to the slight hydrocephalus resulting from the old rickets, and how much to the new disease.

Epidemiology of Pneumonias in Children

Drs. Godfrey R. Pisek and M. C. Pease, New York: From a study of a thousand cases, we have established a mortality rate for pneumonia of 34.3 per cent. Bronchopneumonia is preeminently a disease of the first two years of life, and is relatively uncommon after the third year. Lobar pneumonia is the type present after that period. Omitting those cases which are frankly secondary to some other condition or which occur as a terminal infection, the infection which is the etiologic factor of primary lobar pneumonia is always the pneumococcus; bronchopneumonia may be due to a number of organisms. If pneumococci are present in bronchopneumonia, they are usually one of a group of organisms, or are of low virulence. The pneumonia should be treated with a serum or vaccine derived from organisms belonging to the group causing the infection, or the therapy will be useless.

DISCUSSION

Dr. Julius P. Sedgwick, Minneapolis: At Minneapolis, in hospital, as well as in private practice, the mortality from lobar pneumonia in infants and young children is almost nothing.

Dr. A. D. Blackader, Montreal: A high mortality in lobar pneumonia does not represent the experience we have in Montreal.

Unusual Case of Congenital Heart Disease

Dr. John Lovett Morse, Boston: A child of 4 years had a severe attack. No murmur could be heard by any one, however, except the house doctor. Nov. 30, 1914, he came to the hospital with the history of having been taken suddenly ill the night before. No murmurs or thrill could be heard. On the following day he was not examined, but the day after, Dr. Howland discovered a murmur, which, however, could not be heard by others. December 4, he developed a diastolic murmur, and later, a systolic murmur. This was followed by a double pneumonia. Within the next few weeks, the murmur diminished, but did not disappear. He then died suddenly, presumably from embolism. Only a partial necropsy was obtained, which showed complete atresia of the pulmonary artery, congenital defect of the intraventricular septum, vegetative endocarditis, an open ductus arteriosus, and atrophy of the right ventricle. Only five other cases like this are said to be on record.

DISCUSSION

Dr. Alfred Hand, Jr., Philadelphia: In the few instances in which I have seen such a defect of the septum, the lesion has been in the muscular, rather than the membranous part.

Case of Myelogenous Leukemia in an Infant Nine Months Old

Dr. J. H. Mason, Baltimore: The patient was a girl, aged 9 months. The striking feature in the case, besides the age of the patient, was the rapid course of the disease, less than three weeks. There was no enlargement of the lymph nodes or spleen, and no record of hemorrhage or of necrosis of the mucous membrane. The symptoms apparently were entirely referable to the gastro-intestinal tract. The great number of leukocytes in the circulating blood (200,000 per cubic millimeter) is to be accounted for by a possible peripheral infection. The atypical granulations seen with neutrophilic myelocytes as well as in the presence of eosinophilic and basophilic varieties gave evidence that it was a true primary disease of the bone-forming organs.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

4 *Distribution of Gastrin in Body. R. W. Keeton and F. C. Koch, Chicago.
5 Researches on Exchange of Energy in Live Animal Tissues. I. Microcalorimetry Applied to Animal Tissues. A. O. de Almeida, Rio de Janeiro.

1. **Active Principles of Organs.**—All the different organs from which the authors prepared extracts, with the exception of the suprarenal, contain a depressor substance within the "residue" portion, which in each case varies in its action directly as its nitrogen content (calculated in terms of protein). The depressor effect of the thyroid "residue" is said to be dependent on a substance containing iodin. When standardized according to its nitrogen content each "residue" produces characteristically different effects in the kymograph tracings. This depressor agent cannot be cholin because a dosage of pure cholin which is comparable to that of a thyroid "residue," for example, produces no effect. The active portion of these "residues" is apparently not the same as Popielski's vasodilatin, which is prepared in a totally different way and gives different reactions.

2. **Rate of Oxidation of Enzymes.**—The Burges summarize their findings as follows: Trypsin is more easily oxidized than trypsinogen. Pepsin is more easily oxidized than pepsinogen. The fact that trypsin and pepsin are relatively easy to oxidize makes it possible for the mucosa of the stomach and intestine to protect itself from digestion by means of its oxidative processes. The fact that trypsinogen and pepsinogen are relatively difficult to oxidize prevents these substances from being oxidized in the cells of the pancreas and of the gastric mucosa during the process of secretion.

3. **Epinephrin and Vasomotor Irritability.**—In forty-four anesthetized dogs the effects of epinephrin infusion on the

irritability of the vasomotor mechanism was investigated by Hoskins and Rowley. The vasomotor mechanism was stimulated by faradization of the sciatic and splanchnic nerves, and by injections of nicotin, epinephrin and pituitary extract, before, during and after intravenous infusion with epinephrin. No concentration of epinephrin gave satisfactory evidence of augmenting vasomotor irritability, or facilitating the transmission of vasomotor impulses. In most cases the infusion lessened the vasomotor irritability—sometimes to a marked degree. The animal's own suprarenal glands played no significant part in the results. The irritability of both the pressor and depressor mechanisms was decreased. The authors conclude that the depression was probably both central and peripheral, hence circulating epinephrin is probably not a factor in the ordinary functioning of the animal economy.

4. **Distribution of Gastrin in Body.**—Evaporation of an acid extract from various tissues leaves a residue, soluble with difficulty, in 95 to 98 per cent. alcohol, which manifests varying degrees of gastrin activity. The gastrin is uniformly distributed throughout the stomach mucosa, is found in much smaller concentrations in the duodenum, and its presence can just be demonstrated in the esophagus. Preparations of pancreas, submaxillary gland, smooth muscle and striated muscle are negative. Gastrin intramuscular doses of 1 c.c. (corresponding to 4 to 5 gm. of fresh tissue) cause a fall in blood pressure lasting over four to five minutes, a secretion lasting over one and one-half hours with a maximum between thirty and forty-five minutes following the injection. The authors believe that gastrin causes a true gastric secretion rather than a simple vasodilator response, that it is of a different chemical nature from pancreatic secretin, and that it is a specific substance.

11 Case of Abscess of Liver, Due to Streptothrix. A. Bloomfield and S. Bayne-Jones, Baltimore.

6. **Study of Blood Sugar.**—The Kowarsky method of determining blood sugar, as modified by the authors, affords an efficient and accurate means of studying blood sugar in man. The normal blood sugar, as shown by a study of sixty-one determinations, varies from 0.04 to 0.12 per cent. (in one instance 0.14 per cent.) with an average of 0.084 per cent. These variations are due to the varying factors in the ordinary day of any normal individual—especially to the diet factor. Carbohydrate in the diet raises the blood sugar. The blood sugar of a normal man describes a curve reaching its lowest limits before breakfast and before dinner, and invariably showing a rise one hour after meals. The authors emphasize the fact that blood sugar determinations, to be of any value, must be performed before and after an ordinary meal containing carbohydrate.

12. **Barlow's Disease Experimentally Produced.**—Pronounced cases of Barlow's disease were produced by Ingier in the fetus as early as ten to fifteen days after the commencement of dieting pregnant guinea-pigs with oats and water. There are wide individual variations. The scorbutic changes in the skeleton are greatest in the earlier embryonic stages. The fetuses of that period, with practically no exceptions, die and show marked traces of impeded growth. Fetuses from the later period of pregnancy are born alive, and apparently fully developed, with comparatively slight changes in the osseous system. Even a short extension of the period of extra-uterine dieting on milk from scorbutic mothers and later on oats and water is sufficient to change the latent scurvy into a highly pronounced case. The fetus cannot be kept alive longer than the adult animal, about twenty-eight days, either by intra-uterine dieting alone or by combined intra-uterine and extra-uterine dieting. The mothers show signs of disease at an early period, and are more severely attacked than nonpregnant animals. Death also occurs comparatively often in the first period of gestation.

13. **Cultivation of Vaccine Virus.**—Vaccine virus freed from all associated bacteria by means of suitable disinfecting agents was propagated by Noguchi in a pure state in the testicles of rabbits and bulls. The virus cultivated in this manner is not only devoid of all bacteria, but appears capable of indefinite transfer from one animal to another. Sixty passages in rabbits of a pure strain have been made within one year. Several transfers from testicle to testicle are required to bring about accurate adaptation of the virus to the testicular parenchyma, so that continued propagation in this way can be certainly secured. During the first transfers from testicle to testicle the activity of the virus may be less than the original skin specimen from which the pure strain was derived; but as the transfers proceed the activity rises until, when the adaptation is complete, the activity of the testicular equals that of the skin strain. The multiplication of the virus within the testicle is maximum on the fourth or fifth day after inoculation; the quantity of virus remains about stationary until the eighth day, when diminution begins. At the expiration of five weeks no more virus could be dected in the testicle.

The vaccinal processes in the skin, cornea and testicle of rabbits are practically identical whether the virus employed for the inoculation has been the original skin strain or the pure testicular strain; and the skin lesions produced in the calf by means of the two strains are also identical.

Human beings react to the pure testicular strain of vaccine virus in an entirely typical manner. In the case both of original vaccination and revaccination the vaccinal effects cannot be distinguished from those arising from uncomplicated skin virus. Pure strains of testicular virus are readily produced, and once secured they may be propagated in a pure state in rabbits or bulls by the method described, without difficulty and with economy. The pure strains thus obtained should supply an ideal form of virus for employment in the vaccination of human beings.

14. **Transplantation of Tumors to Foreign Species.**—By feeding to rats the tissue of the mouse chondroma, Funk found that they are rendered more suitable as hosts for the growth. Using this method rats have been inoculated successfully with the mouse tumor, and it has been transferred to three successive series of these animals.

15. **Effect of Arsenic Compounds on Rous Chicken Sarcoma.**—Arsenic and arsenious acids, cacodylic acid, atoxyl and neosalvarson failed to influence markedly the growth of the Rous chicken sarcoma.

16. **Antibody Formation.**—It is shown by Zinsser and Hopkins that the serum of rabbits treated with emulsions of *Spirochaeta pallida* contains agglutination substances.

17. **Adult Tertian Malarial Parasites.**—It is claimed by Lawson that the malarial parasite is extracellular throughout its entire life cycle; that is, when it is not free in the blood serum, it is attached to the external surface of the red corpuscle. Adult parasites follow the same procedure in attaching themselves to the outer surface of the red corpuscles, as do the young parasites. Adult parasites are most frequently seen attached to surface corpuscular mounds. Corpuscular mounds projecting at the periphery of the red corpuscles and encircled by the pseudopodia of adult parasites, are proof positive of the extracellular relation of the adult parasite to the red corpuscle. Adult parasites attached to peripheral corpuscular mounds are only found in appreciable numbers when the red corpuscles are not badly damaged, so that the mounds show more or less hemoglobin content. The nuclei or protoplasm of adult parasites extending beyond the periphery of the red corpuscles is additional evidence of the extracellular relation of the parasites to the red corpuscle.

18. **Influence of Digitalis on Human Electrocardiogram.**—It is shown in this investigation that digitalis, administered orally to patients, can modify the T wave in the electrocardiogram. When the T wave in the initial curve is directed upward, the first change noticed is a lowering and the final change is an inversion of the wave. It is not only the wave itself, but that portion of the curve between the end of R and the end of T which is involved. Instances in which the initial T waves have other than upright forms are described and their behavior under the influence of digitalis has been indicated. This influence of digitalis on the T wave may be detected in thirty-six to forty-eight hours after the administration of digitalis has commenced; it may persist as long as twenty-two days after the administration has been stopped. Instances in which it persisted only five days have been encountered. The unexpected length of duration of the sign probably explains why a second treatment with digitalis requires a smaller amount of the drug to produce the same effect than the first.

19. **Experimental Pneumonia in Rabbit.**—Kirkbride's study would seem to give some ground for the view that while in pneumonia a hypersensitive condition probably takes some part in the inception of the infection, the subsequent development of the diffuse exudative reaction in the lung is not directly due to an acquired hypersusceptibility, but to intrinsic qualities possessed by the pneumococcus itself.

21. **Pathogenic Properties of Bacillus Proteus.**—The first proteus strain with which Larson and Bell experimented was isolated from a laparotomy wound in a case which subsequently terminated fatally. The proteus was repeatedly isolated from this patient in pure culture. The second strain was isolated from a severe eye infection following a cataract operation. A third strain was isolated from an infection of the finger, believed to have been contracted at a necropsy. A fourth was isolated from the heart's blood in a case in which the patient had died from peritonitis following a gunshot wound of the intestines. The fifth strain was from a patient with gangrene of the lung. These organisms all proved to be pathogenic for rabbits. All cultures obtained from sources other than human infections were nonpathogenic for the laboratory animals. A nonpathogenic culture may be made pathogenic by the use of aggressins or by inoculation into the anterior chamber of the eye. Proteus cultures lose their virulence rapidly when grown on artificial mediums. The lesions produced in animals are either simple abscesses, proliferative lesions, or a mixed exudative and proliferative lesion. The proliferative lesions consist mainly of epithelioid cells apparently of connective tissue origin. No giant cells of the Langhans type are present. The histologic type of the lesion does not depend on the strain employed. Neither does it bear any relation to the clinical severity of the case. The ability to produce the characteristic lesions has no necessary connection with the toxicity of the bacteria. The authors suggest that the proteus bacteria probably play a more important part in human pathology than is generally believed.

Titles marked with an asterisk (*) are abstracted below. Single case reports and trials of new drugs are usually omitted.

British Medical Journal, London

May 22, I, No. 2838, pp. 877-916

1 *Treatment of Toxemia of Later Pregnancy; Report of Cases. J. Byers.
2 Dressing Station in France. G. R. Ward.
3 Some Infections of Tonsils. F. C. Pybus.
4 *Successful Sterlization of Skin with Tincture of Iodin. J. L. Stretton.
5 Typhus in Palestine, 1913 to 1914. C. H. Corbett.
6 Admission of Men with Glasses into Army. A. A. Bradburne.

1. **Treatment of Toxemia of Later Pregnancy.**—Byers emphasizes that every effort should be made to relieve the kidneys by getting the skin and bowels to act and by the administration of a simple nonnitrogenous diet. If there be headache or edema the patient, in addition, should be kept in bed and should have hot baths, free purgation and a milk diet; and if the state of affairs becomes more severe, warm saline lavage of the stomach and intestines is useful. In the nephritic cases, if in spite of this method of management the patients get worse, labor should be induced. One of the most important points emphasized is that a pregnant woman's urine must be analyzed once a month during the first six months of gestation, and at least once a fortnight after that period. Since adopting this routine method, Byers has not had in private practice during the past fifteen years a single case of eclampsia, as prompt measures taken when an examination of the urine showed any considerable amount of albumin (under these circumstances a catheter specimen should always be obtained), and with it any diminution in urea and nitrogen output, warded off all risk of convulsions and coma.

4. **Sterilization of Skin with Iodin.**—Stretton claims to have been the originator of this procedure, which he first described Aug. 14, 1909. He has now used the method with satisfaction in upward of 3,000 cases, and has never seen any dermatitis result from the use of the tincture of iodin. There is sometimes a limited amount of desquamation. The solution he originally used was the tincture of iodin (B. P.). It is prepared by dissolving 2.5 per cent. of iodin and 2.5 per cent. of potassium iodid in rectified spirit. In an endeavor to save the funds of the hospital he tried a solution of the same strength in methylated spirit, but soon found that it produced so much irritation and lacrymation that he was obliged to resume the original compound. He now uses the *tincture in the theater and a similar solution made with* methylated spirit in the wards.

12 *Two Extraordinary Cases of Liver Abscess. C. B. Pasley.
13 Cerebrospinal Fever and Sphenoidal Sinus. D. Embleton and E. A. Peters.

7. **Some Infections of Tonsils.**—The principles to be adopted in the treatment of tonsillar disease are summed up by Pybus as follows: So far as the individual is concerned, when the symptoms are mainly or entirely mechanical and fail to subside in three months after removal of any source of infection, partial removal may suffice. Tonsillotomy, however, has this disadvantage, the basal portion of the tonsil may enlarge and again cause symptoms. In addition to this, many hypertrophied tonsils, so far as can be ascertained on inspection, do not appear to be grossly infected. In those cases which are grossly infected the basal portion, often the most diseased, is left behind and may commence to give trouble, especially if some of the lacunae become partially or entirely sealed up in the process of healing. When infec-

tive symptoms predominate in the tonsil itself, such as acute tonsillitis or chronic lacuna infection, or when the tonsils are in addition enlarged, any source of infection must be removed, especially carious teeth. Nasal breathing must be reestablished, and the case watched to see the effect of the treatment. In cases in which the tonsil is too severely affected to be capable of recovery, as judged by the recurrence of symptoms and the failure of the above measures, then total removal is indicated.

For lymphatic gland infections, in which tuberculosis is suspected, tonsillectomy is indicated; the course of the glandular enlargement determines whether this also may require operation. In pyogenic infections of the glands the tonsil must be dealt with when the acute lymphadenitis has subsided or been operated on if suppuration has supervened. Chronic glandular enlargement of the mild or moderate degree is so frequently encountered in hypertrophied tonsils that when the tonsil recovers its normal character the glands subside also. It should be a rule that no tonsil should be removed when acutely inflamed. For more distant infections, when the tonsil is suspected of being the focus, removal is indicated when the general condition is satisfactory. The maintenance of nasal respiration, the prevention of dental caries and the proper supply of food in sufficient quality and quantity will greatly diminish the prevalence of this condition. The provision of a cleaner air supply and the prevention of infection by milk are measures needing attention.

9. **Heart Perfusion with Excretory Toxins.**—The heart is exposed to the action of certain excretory toxins of the urine and feces when the mechanism of their expulsion is defective, or it may be, to these toxins of their precursors normally on their way to elimination. This action was tested by Barry by perfusion of the toad's heart. The inferior vena cava below the liver was isolated and a small cannula inserted, communicating with three perfusion bottles; one contained freshly prepared Ringer's solution, the second a mixture of human urine and the third fecal extract made with Ringer's solution. Strengths of 10 and 15 per cent. were tried. The aorta was cut across to provide a free exit of the fluid. The toxicity of these solutions is greatly diminished by boiling and by allowing them to stand for a few days.

The first toxic effect is exhibited by the ventricle. A 10 per cent. urine solution in a few seconds brings about cessation of this chamber in a state of tonus. The auricular beat is increased in force, due in part, at any rate, to increased tension; there was no previous perfusion. Recovery with Ringer's solution is rapid, though the ventricle is somewhat irregular for a time. Fecal extract shows a similar result. There seems to be a certain degree of tolerance of, or immunity from, the toxins on their repeated use. This is exhibited by a slower onset of the effects and a diminution of the toxicity. A certain amount of antagonism seems to exist between these poisons, but the question has not been properly investigated. The a.-v. bundle seems to be the part most affected by the excretory toxins which depress its conductivity, at the same time that they affect somewhat the ventricular muscle as a whole. A marked difference in the mechanism of the two chambers is also demonstrated by their action. Irritability of ventricular muscle is completely lost only with strong solutions and is quickly recovered if the action be not too long continued. The nervous mechanism, except the accelerator fibers, seems to be unaffected by the weaker solutions.

12. **Two Extraordinary Cases of Liver Abscess.**—In the two cases cited by Pasley as worthy of record from the fact of the remarkable size of the abscesses, the patients were extremely emaciated and constitutionally extremely ill. They both recovered perfectly, thus showing that no liver abscess, however large and however ill their possessors may be, can be considered as hopeless. In one case the abdomen was found enormously distended, resembling closely the abdomen at full-term pregnancy. An enormous tumor was palpable, which gave the sensation of fluid under extreme pressure. It was slightly tender to touch. Absolute dulness extended from the pubic region up to and continuous with the hepatic area proper. The tumor extended equally into both umbilical regions laterally—in fact, it practically filled the abdominal cavity. The patient's general condition was extremely bad; he was wretchedly thin, weak and listless. There was absolutely no sign of jaundice and no bile in the urine. Blood examination showed slight leukocytosis. Examination of stools gave a negative result. A provisional diagnosis of liver abscess was made and operation decided on. The patient rapidly improved. No ameba were found in swabbings taken from the abscess cavity. The only medicine given during his illness was emetin administered daily by hypodermic injection. He received 1½ grains per day.

In the second case, on examination, an enormous tumor was found practically filling the entire abdomen. It gave the sensation, on palpation, of a sac containing fluid under very high pressure. So far as could be made out by external palpation the lower margin of the tumor was situated 1½ inches above the symphysis pubis. It extended laterally into each flank and seemed to originate from the liver. Examination of the blood showed a slight leukocytosis. Examination of the feces showed the presence of ankylostoma and ascaris ova. The patient's general condition was wretched. Pasley operated on him. His recovery was uneventful. He received one-half grain emetin hydrochlorid daily for three weeks by hypodermic injection.

17 *Treatment of Acute Diffuse Peritonitis. S. Mercadé.
18 Suppuration in Hand Spreads by Continuity or by the Lymph Vessels. (Pathogénie des phlegmons de la main.) L. Imbert.

17. **Acute Diffuse Peritonitis.**—Mercadé discusses in turn the treatment of the peritoneum after the inevitable laparotomy, the treatment of the general intoxication, treatment also of the paralysis of the bowel and stomach, and treatment of the heart weakness. To combat the general intoxication lavage of the blood is required, and this is best realized by saline solution given in the rectum by the drop method. Some prefer plain boiled water, others sea water; the latter seems to have a pronounced stimulating action, but does not promote diuresis so well as plain water. Solutions of sugar, he says, have little diuretic action, but are nourishing, stimulating and tonic. Schiassi advocates for the purpose a solution of sodium chlorid 6.5 parts; potassium chlorid, 0.3 part; fused calcium chlorid, 1 part; sodium bicarbonate, 0.5 part; glucose, 50 parts; alcohol, 15 parts, and distilled water, 1,000 parts.

Among the nine various measures that can be applied in treatment of paralysis of the bowel, he emphasizes the advantages of electric enemas. They seem especially indicated here to combat the dynamic ileus; they are harmless and if they prove effectual their action is prompt. They should be applied early, so as not to waste much time if they prove ineffectual after two or three applications. If the paralysis extends to the stomach, a retention stomach tube is advocated by Grosser and others, the tube, 4 or 8 mm. in diameter, passed through the nose. Sometimes as much as 4 or 5 liters of fluid are thus brought out of the stomach in the twenty-four hours, and fluids must be supplied in other ways to replace these amounts thus lost. In conclusion, Mercadé points out that we have thus quite a number of measures at our command for carrying a patient through acute general peritonitis, but too many must not be applied at once.

May 13, No. 21, pp. 161-168

24 *White Spots in the Mouth Usually a Sign of Syphilis. (Les taches blanches de la muqueuse jugale et commissurale, dites "plaques de fumeur," fonction de syphilis.) L. Landouzy.
25 Splint in Treatment of Radial Paralysis. T. Tuffier.
26 *Peritoneal Complications of Typhoid. M. Villaret.

20. **Wounds of Peripheral Nerves.**—Imbert comments on the number of operations now required for wounds of this kind as one of the surprises of the war. He is stationed at Marseilles, and has had to devote three or four mornings a week to operations on peripheral nerves. He does not operate on the nerve until the wound has entirely healed, but then permits no further delay. The study of each case requires the cooperation of a neurologist and histologist with the surgeon. When this is the case the danger of the operation is minimal while the functional outcome is often extremely gratifying.

24. **"Smoker's Patches" in the Mouth.**—Landouzy makes a practice of examining the mouth for the whitish lines or triangular patch on the mucosa extending back from the juncture of the lips toward the first molar known as smoker's commissural patches. He has found them exclusively in syphilitics; the tobacco is merely the local irritant causing the patch to develop in the predisposed. He has found them in women, but never in any except those married to syphilitics or with a history of personal syphilis. Landouzy has been preaching for twenty years the extraordinary, the unbelievable frequency of syphilis, and has found these smoker's patches often the only clue. He examines the mouth of every adult patient, man or woman, and has found these patches on the inside of the cheeks almost constantly in syphilitic smokers, and with extreme frequency in nonsmoking syphilitics in the third phase of the disease, and also in syphilitic women. The patches are liable to retrogress under mercury and iodid, although the smokers make no change in their smoking habits. Since the introduction of the Wassermann test, he applies it regularly to all patients showing these stripes or patches in the mouth. Of 164 syphilitics, the Wassermann was strongly positive in 81 of the 131 showing the patches. In another group of 72 men and 12 women in the third stage of syphilis, 52 of the men and 4 of the women had white patches, and 39 of these men and 2 of the women responded positively to the Wassermann test. He found the commissural leukoplakia also in 15 of 17 young syphilitic soldiers recently encountered; the Wassermann was positive in 9. In short, Landouzy regards these "smoker's patches" as pathognomonic, and as instructive as the Wassermann reaction, while their presence can be determined by merely a glance. He adds that the number of women in whom he has found them now total 15.

26. **Peritoneal Complications of Typhoid.**—Villaret states that perforation has occurred in only about 1.5 per cent. of the 600 cases of typhoid among soldiers in the hospital in his charge, but that all the other possible immediate complications of typhoid were numerous and grave. A purulent otitis or parotitis seemed often to serve as a spontaneous fixation abscess, and hastened recovery. Unless perforation had actually occurred, medical measures brought the men through in 97 per cent. of the cases showing a reaction on the part of the peritoneum. When signs of such a reaction develop, absolute repose and absolutely nothing by the mouth for several days are indicated; the mouth can be frequently rinsed out, and that is all. Ice to the abdomen and over the heart was an important aid in the cure, he is convinced, as also subcutaneous injections of 0.5 or 1 c.c. of a 1:1,000 solution of epinephrin or of 300 or 500 c.c. of saline containing epinephrin. The great value of these injections whenever cardiovascular or peritoneal symptoms became apparent was demonstrated most effectually in the aggravation of conditions throughout the wards when the supply of epinephrin ran out. A tendency to collapse was combated with camphorated oil plus ether, and the septicemia with some colloidal silver preparation subcutaneously, and an artificial fixation abscess. These measures cured 60 per cent. of the men with unmistakable peritonitis, and 97 per cent. of those with a peritoneal reaction which did not progress to actual inflammation.

Berliner klinische Wochenschrift

May 17, LII, No. 20, pp. 509-536

27 *Angina Pectoris. H. Kohn.
28 *Heart Disturbances in War. (Herzstörungen bei Kriegsteilnehmern.) S. Korach.
29 *Vagotony. W. Lublinski.
30 Scientific Management in Factories, Etc., from Psychologic Standpoint. (Zur Psychologie des Wirtschaftslebens.) G. Rosenfeld.
31 *War and Venereal Diseases. (Krieg und Geschlechtskrankheiten.) K. Touton. Commenced in No. 19.
32 Spa Treatment of the Wounded. (Resultate der Badebehandlung von Kriegsverwundeten und Erkrankten.) M. Porges.
33 Bath Trains. (Transportable Badeanstalten.) R. Rauch.

27. **Angina Pectoris.**—Kohn remarks that although Askanazy's work on the efficacy of theobromin in angina pectoris was published twenty years ago, yet few even now realize that theobromin can be relied on in angina pectoris almost as confidently as digitalis can be relied on when the heart action is rapid and weak. In treatment of a pronounced attack of angina pectoris, morphin relieves the pain and relaxes the spasmodic contraction of the coronary arteries. The dose must be 0.01 gm. at least, repeated if improvement does not soon follow. If one already knows the patient, 0.015 or 0.02 might be given to start with. If the pulse is slow or growing slower, stimulants should be injected at the same time, not waiting for signs of pulmonary edema to develop, repeating the camphor or caffein at need. Alcohol can also be used, with moist heat to the heart, placing the hands or feet in hot water, and giving amyl nitrite or nitroglycerin. To ward off attacks, theobromin has fully established its efficacy, he says, in treatment of the fundamental disturbance of which the angina pectoris is the manifestation. It is actually marvelous, he declares, to witness how the theobromin arrests the tendency to repeated mild partial or abortive attacks, the status anginosus as he calls it, in analogy with the status epilepticus. Patients long tormented day after day or night after night, are freed at once from their symptoms by the theobromin. He deplores the lack of general appreciation of the efficiency of theobromin in the treatment of the fundamental disturbances which are the bases for angina pectoris. The patient must stay in bed till all tendency to heart disturbances seems to have subsided; physical exercise should be discouraged and tobacco forbidden.

28. **Soldier's Heart.**—Korach remarks that in scarcely any other affection is it so difficult to decide whether the symptoms are of organic or purely nervous origin as in the heart disturbances encountered among the men in active service. And yet dire harm is likely to be wrought if treatment is applied on the wrong basis. The majority of the men he has seen at Hamburg who were sent back from the front on account of cardiovascular disturbances were suffering merely from purely nervous or functional cardiovascular derangement. Once entirely relieved from physical and emotional stress, the disturbances slowly right themselves in those with previously sound hearts. Differentiation is possible as a rule only with prolonged tranquil study of the case. Neurasthenics with extra systoles and very high blood pressure are not capable of service at the front.

29. **Vagotony.**—Lublinski goes over much the same ground covered by the two articles in The Journal, Jan. 31 and May 16, 1914, pp. 365 and 1535, and emphasizes that it is easy to recognize the "vagotoniker" at a glance by the ebb and flow of color in the face, the sudden perspiration, the

cool, damp and bluish hands, the lusterless eyes, the narrow pupil, the drooping corners of the mouth and the frequent swallowing. The abnormally irritable vagus system can be steadied and toned up with atropin, but this must be kept up perseveringly, even when good results are apparent, with ascending and declining dosage. Arsenic is useful also as a tonic for the nerves; it is especially advantageous in the form of an arsenical mineral water.

31. **War and Venereal Diseases.**—This long address was delivered before a mixed audience, and in conclusion Touton reiterated that the compulsory introduction of individual prophylactics is, next to sanification of prostitution, by far the most important means to avoid the weakening of the army from venereal diseases. He quotes a communication from Löb at Mannheim to the effect that under the influence of salvarsan endemic syphilis had been nearly stamped out in that city, as in other smaller centers, but that since the war began there has been an appreciable increase in the number of cases of syphilis. Touton advocates classing the effects of venereal diseases acquired during the war with other war disabilities entitling to a pension. The state insurance has abandoned its former practice of discriminating against such policy-holders, and he urges that soldiers and their families suffering from the results of these diseases should not be treated as criminals or sinners. In short, he concludes, the whole subject of venereal disease during the war should be regarded and managed from the strictly hygienic-medical standpoint, leaving all ethical and esthetic considerations in the background for the time being.

Gazzetta degli Ospedali e delle Cliniche, Milan

May 13, XXVI, No. 38, pp. 593-608

34 *Aleukemic Lymphomatosis. (Le linfosi aleucemiche dal punto di vista clinico.) G. Ghedini.
35 Treatment of Tetanus in the Present War. A. Bertolini.

34. **Aleukemic Lymphosis.**—Ghedini recalls that lymphosis may develop with merely the signs and symptoms, local and general, of more or less severe anemia, with or without enlargement of the spleen, or as a hemorrhagic diathesis, an acute infection, simple lymphadenitis, sarcomatosis of the viscera or bones, or a nodular infiltrating and ulcerating dermatosis, or it may simulate syphilitic or tuberculous lesions. He reports a specimen case of each of these ten different types, and refers to typical examples of each on record. It is evident from his reasearch that in many cases of anemia, with splenomegaly, the underlying lymphomatosis has not been recognized. It may develop with the aleukemic blood picture, and the latter may vary widely from the classical type of lymphomatosis. The morbid blood picture should be studied from a broader standpoint than has hitherto been the case. It should be studied not merely as a disease of the blood-producing apparatus.

Policlinico, Rome

May, XXII, Surgical Section, No. 5, pp. 209-264

36 *Experimental Study of Fat Embolism. (Embolia grassosa.) M. Maccagno.
37 *False Appendicitis. L. Longo. Commenced in No. 4.

36. **Fat Embolism.**—Maccagno injected from 0.5 to 1.5 c.c. of olive oil into a vein in eleven rabbits and the next day killed and examined them to learn the fate of the oil. In others he repeated the injections and did not kill the animals until several days later. Study of the forty-two rabbits thus treated shows that the animals are unable to survive after intravenous injection of an amount equal to 1.06 per thousand of the weight. Also that the fat is only very slowly and defectively eliminated; he found it still present by the fortieth day. The most notable results and those most liable to prove fatal, are pulmonary edema, infarcts, embolism and heart disturbances. The experiences related teach the necessity for absolute repose in cases of fracture suggesting the possibility of fat embolism. Everything should be avoided that might in any way favor the passage of fat into the blood. When a fracture has not been reduced at the time the symptoms of fat embolism are observed, it is better to refrain from further intervention to reduce the fracture until the vessels have become thrombosed, as even a small quantity of fat in the blood vessels is likely to do much damage.

37. **Pseudoappendicitis.**—By this term Longo means any clinical picture which may be mistaken for that of appendicitis. The treatment of course differs for each, but the decision can be made, as a rule, only after the abdomen has been opened. It is especially necessary to examine the surrounding viscera when the appendicitis seems to have started in as a chronic affection and the appendix seems practically sound on direct examination. Besides this type of chronic appendicitis, there is a type in which the symptoms are many and varied, but the appendicitis never becomes fully developed; this group may be called abortive appendicitis. In other cases appendicitis is simulated by the disturbances resulting from Lane's kink; from Jackson's membranous pericolitis; mucomembranous enterocolitis with paroxysmal attacks resembling appendicitis, or the disturbances resulting from abnormal movability and dilatation of the cecum. He reports seven operative cases of this pseudoappendicitis, the operation revealing the appendix nearly or quite sound; in three cases the trouble was a simple membranous pericolitis, in the others the result of dilatation or abnormal movability of the cecum, or pericolitis with complications. The operations had been done in some of the cases on the diagnosis of ileus.

Hygiea, Stockholm

LXXVII, No. 8, pp. 401-464

38 *Present Status of Progressive Paralysis and Tabes. (Luesparalysläran i dess nuvarande läge.) V. Wigert.
39 Case of Erythema with Intense Tuberculin Skin Reaction. K. Frumerie.

38. **Present Status of Paralysis and Tabes.**—Wigert gives tables from the literature showing the proportion of cases of syphilis in which tabes or general paralysis had developed, classified according to the treatment that had been given. It is much to be regretted that the statistics cannot be compared with each other, as the reports vary so widely with respect to numerous points. It is high time, he declares, for compilation of statistics on a uniform basis in order to learn the exact conditions which favor or render impossible the development of tabes and general paralysis later. Cases should be classified in groups with like clinical course and unlike treatment, and also in groups with like treatment and unlike course of the disease. No such compilation is available at present. Certain statistics seem to indicate that treatment actually shortens the interval between infection and the appearance of paralysis or tabes, and this question deserves intensive study. Only one fact seems to stand out as established by the records to date, he remarks, that there is no evidence on hand at present that the usual mercurial treatment of fifteen and twenty years ago had any efficacy as a relative protection against paralysis and tabes. About half the article is devoted to a discussion of the existence of a syphilitic virus with a special affinity for nerve tissue.

Ugeskrift for Læger, Copenhagen

May 20, LXXVII, No. 20, pp. 781-824

40 *Physiology and Pathology of Sports and Competitive Athletics. K. Secher.
41 Medicinal Rash. (Tilfaelde af Atophanexanthem.) A. Kissmeyer.

40. **Competitive Athletics.**—Secher has not found much evidence of harm done by sports and athletics in Denmark, but he thinks that the authorities should interfere to enforce a medical examination before any competitive event of the kind. A number of athletic associations have already provided for this as a routine measure. All athletics should have some medical supervision. By this means it would be possible to keep out of strenuous competitive events those not equal to this strain, although under ordinary conditions they can keep up their athletic work without harm.

Miscellany

Cystitis in Children

R. Fischl is professor of children's diseases at the University of Prague, and in a recent number of the *Prager medizinische Wochenschrift* he reviews his experiences with cystitis in children, especially the cases in which he has been called in consultation and the attending physician had failed to diagnose the bladder trouble. In his service at Prague, every girl child suspected of urinary trouble is catheterized, and boy babies wear a special receptacle to collect the urine. By this systematic investigation, he has found that cystitis is comparatively rare. Only twenty-six cases were found among the 15,000 children examined in the course of twelve years, and in the group were no infants less than a year old. He has also encountered fifteen cases in his private practice, a total of forty-one cases. Only five of the patients were boys. In twelve cases, the family had recognized that the bladder was the seat of the trouble, but in over 50 per cent. of the cases, this had not been suspected. One child of 8 was supposed to have typhoid, as there had been high continuous fever for a week with moderate diarrhea. There was no agglutination, and the only signs of trouble were slight enlargement of the spleen. The urine at first had contained a little albumin, and this gave the clue to the cystitis; under treatment for this the child promptly recovered. In another case of apparent typhoid, the child of 9 had been taken suddenly, after a long walk on a hot day, with high fever and prostration soon accompanied by diarrhea and cough. The aspect and symptoms suggested typhoid except that there was no agglutination; the sudden onset was also unlike typhoid. The discovery of a vulvovaginitis suggested the possibility of bladder trouble, the long walk having possibly contributed to spread the infection to the bladder. Treatment on this assumption soon cured the child.

Another young child had been treated for supposed typhoid for weeks without benefit, while the strict dieting had emaciated the little patient. The fever had been continuous at first and then irregularly remittent. Called in consultation, Fischl noticed the peculiar odor of the urine at once, and the microscope showed evidences of cystopyelitis. It had developed after an attack of diarrhea. As it had not been suspected for so many weeks, it had run into a chronic phase quite refractory to persevering local measures plus hexamethylenamin internally. These brought the temperature down to normal and the general condition improved, but the urine kept turbid and of a putrid odor while the child had the tint of anemia. The urine finally became normal after one injection of an autogenous colon bacillus vaccine, and there has been no relapse to date.

Left untreated too long, cystitis may drag along for years, or lie latent until roused by pregnancy or other period of stress. Fischl warns that urates in the urine are liable to simulate the cloudiness of cystitic urine. Powder used to dust the genitals of infants may also get into the urine and prove misleading. In one case a bright 5-year-old boy became incontinent and wet his clothes both day and night. The enuresis was not affected by the various methods of treatment applied in turn. No one thought of examining the urine under the microscope. When finally this was done, findings suggestive of cystitis pointed the way to a prompt and speedy cure of both the cystitis and the enuresis.

Fischl gives hexamethylenamin internally in doses of at least 0.5 gm. per day for young infants, and keeps it up until the urine is normal; a week usually answers the purpose. If the desired result is not attained in one or two weeks, it is useless to keep it up longer, and local measures should be applied. He begins with a weak solution of potassium permanganate. If this proves ineffectual, he changes to a 1 : 5,000 silver nitrate solution. The fresh urine with cystitis is so often neutral that there is no reason for treating with alkalies, as Thomson advocates.

Effect of Pasteurization on the Cream Line

Complaints were made to the New York City Board of Health, following the enforcement of certain regulations concerning the temperature at which milk should be pasteurized by milk distributors, that the cream did not properly rise or separate in the pasteurized product and show a distinct line between the cream and the milk. In order to determine the effect of pasteurization at different temperatures and for different periods, a series of tests was instituted under the supervision of the New York board at the different pasteurizing plants, using different methods and different apparatus, and the results are set forth in Reprint 27 of the board by Charles H. Kilbourne, supervising inspector of foods. Details of the tests, the temperatures, apparatus, time and other conditions are given in detail, and some obscure and as yet not entirely explainable phenomena are described in respect to the cream line in the pasteurizing process. The results, however, are summarized by Kilbourne as follows: All tests indicated that when the milk is cleaned by a centrifugal clarifier, the volume of cream in the milk is reduced from 2 to 3 per cent. The volume of cream in bottled milk is influenced by (1) the temperature to which the milk is heated; (2) the length of time the milk is held at the high temperature; (3) the temperature of the heating medium with which the milk comes in contact during the heating process; (4) the clarification of the milk; (5) the type of apparatus used in treating the milk, and (6) the amount of agitation to which the milk is subjected, especially while hot. The last factor is said to have considerable influence, and in one instance in which the cream line was considerably reduced in the process, the experiment was made of reducing the speed of the agitator which kept the hot milk in motion, when it was found that the cream line remained normal. It was also found that in the processes in which there was most agitation or pumping of the hot milk, most difficulty with the cream line was experienced. Other factors which have an influence are said to be the age of the milk before pasteurization, the grade of cows producing the milk, and the freezing or nonfreezing of the milk before being treated. It is stated that milk may be heated to 145 F. for thirty minutes without producing any injurious effect on the cream line.

Sanitary Works in Argentina

The manner in which the problems of water supply and sanitation have been met in Argentina, particularly in Buenos Aires, is described in *Commerce Reports* for April 14. Buenos Aires is said to present points of resemblance to Chicago. Both are decidedly modern cities which received their greatest accessions of population in recent years, and each is situated on a large body of fresh water. In respect to water supply and drainage, Buenos Aires has the advantage over the northern city in that the waters of the Rio de la Plata move toward the sea, and that the winters in Buenos Aires are never so cold that the danger of frozen water pipes and mains needs to be reckoned with.

The scientific study of water supply and drainage for Buenos Aires dates from 1873, when the population was something over 200,000 (it is now over 1,500,000). The sanitary work now partly completed and partly still under construction is supposed to insure a proper drainage and water supply to meet the city's needs up to 1952, at which time it is prophesied that the population will be near to 6,000,000. The consumption of water allowed per inhabitant per day is 300 liters (nearly 80 gallons), an amount considerably above the rate of the actual present consumption.

While some of the water used in Buenos Aires is as yet obtained from driven wells, these are to be done away with and the entire city supplied with water from the Rio de la Plata. By means of sedimentation, coagulation and filtration, it has been found possible to purify the river water absolutely and render it suitable for all purposes.

Since Buenos Aires is situated on the edge of the river, with no natural elevation from which distribution of water to the city might be effected, it has been necessary to construct elevated distributing stations. Four new centers of distribution are planned. From a water tower in the river, an intake tunnel will conduct the water to the pumping stations on shore, whence it will pass, first to the decanting reservoirs, then to the filter beds, and thence to the gravity tanks and reserve tanks, from which a network of water mains will lead it to all parts of the city. The capacity of the tanks, compared with the amount of water consumed in one day, is much less than in New York or London, owing to the high price of land in Buenos Aires and the lack of natural elevations, which have rendered the cost of such large tanks prohibitive. The use of the coagulation method has counterbalanced this difficulty, however, and provision has been made for a proper reserve of filtered water, so that the city will not suffer for water in case the filter beds and coagulation tanks should be temporarily out of service.

The sewage of Buenos Aires is discharged into the Rio de la Plata at a point far enough below the intake to preclude the possibility of contamination of the water supply.

The water supply and drainage of the federal district (Buenos Aires) is under the control of the National Department of Sanitation (Obras Sanitarias de la Nación) which may also, at the request of the provincial cities, undertake similar work on their behalf. This department is autonomous. being responsible only to the president of the republic, who, with the approval of the senate, appoints the members of its directorate, consisting of a president, a vice president and five other members who serve for a term of four years. This directorate is given liberal powers, both administrative and financial. It has the authority to nominate and discharge all subordinates and to raise money, when necessary, for constructive work, by means of loans secured by the property of the department. These loans are finally to be discharged from the income of the department, which is drawn in part from the national lottery and in part from monthly taxes on all houses which receive water and sewage service. These taxes consist of 3 per cent. on the rental value for the water and 2 per cent. for the sewage. This income is sufficient to meet amortization and interest payments and finally to wipe out the entire debt contracted for the work under process of construction.

The Death Rate in Berlin Last Year

The mortality in Berlin was a little higher in 1914 than in 1913; per thousand inhabitants, 14.54 per cent. died in 1914 to 13.48 in 1913. In this calculation, however, the great changes in the populace after the outbreak of the war must be borne in mind. The increase in the mortality for 1914 included 996 males and 592 females, but classifying the deaths by ages shows that the increase was mostly among infants or the aged. This grouping is evident also in the classification according to the causes of death. The increase, namely, is in catarrhal bowel troubles and diarrhea, measles and pertussis, while the figures for scarlet fever and diphtheria are about the same. There was a moderate increase in the mortality from pulmonary tuberculosis, which does not affect to such an extent the very young or the very old. The pneumonia mortality showed a considerable increase, mostly among the elderly. The number of deaths from senile debility also materially increased, as also the number of deaths from cancer.

The influence of the seasons is instructive. In 1914 the mortality in the winter and spring was above the average; from June to November it was moderate. It used to be the rule that the summer months had the highest mortality on account of the high death rate among infants in the heated term. But now the mortality among infants does not form such a large proportion of the total—partly owing to the influence of the declining birth rate—and hence it is not so important a factor in the general mortality.

During 1914, notwithstanding the unusual decline in the birth rate, the infant mortality was notably higher. There were 5,846 deaths among infants, 37,493 living children born in 1914 to 5,607 deaths, and 40,481 living children born in 1913. But even taking this into account, July, August and September, although they showed the highest death rate among infants, did not have so high a total mortality as the months of the winter and spring. The total rate in July was only 13.66 per thousand, the lowest month in the year. More than the heat of the summer, the inclement weather of the winter and early spring claimed more victims in 1914.

Opportunities for Graduate Work

An interesting sketch of medical impressions on a trip around the world was published recently by Dr. J. Eduque in the *Revista Filipina de Medicina y Cirujia* on his return from a tour for inspection of the clinics and hospitals of Europe and America, made under the auspices of the University of the Philippines. In conclusion Eduque summarizes his impressions in the advice to go to Austria to study pathology, diagnosis and specialties, to England for anatomy and physiology, to France for urology and to the United States for surgery. He urges the necessity for studying the language before leaving home, and strongly advocates the joining of the local medical association open to foreigners, as this provides numerous advantages in the way of opportunities and information. His sketch is republished in the *Prensa Medica* of Havana. He relates that the queen of Bulgaria had planned to come to America and bring several young women with her to study the system of trained nurses here as she had been much impressed with their work in the Red Cross units during the last Balkan War.

The Hospital for Industrial Diseases in Italy

The hospital and clinic for the exclusive study and treatment of the industrial diseases, at Milan, has just completed its fourth year of work. It is the first and to date the only institution of the kind for occupational diseases, and the postgraduate courses have attracted medical men from other countries. Prof. L. Devoto is director and is editor of the little monthly, *Lavoro*, published by the clinic, although antedating it by four years. The expense of running the hospital and clinic is $17,000 a year. The number of days of hospital treatment has averaged 18,720 per year. In April, as an average month, 228 persons were given treatment in the dispensary, including 98 women; and 16 men and 14 women were admitted to the hospital. Wassermann tests were applied in 43 cases, with positive findings in 15. Roentgen-ray examinations were made in 63 cases—all without charge. The institution has prepared sets of lantern slides which they sell for $4 a dozen. They portray various features of industrial diseases and means to recognize and avoid them, tables of statistics, etc., from various countries, and other data bearing on occupational disorders.

Biologic Diagnosis by Means of Intermediate Host

E. Brumpt is professor of parasitology in the medical school at São Paulo, Brazil, and he has recently worked out a method for diagnosis which he calls xenodiagnosis, from the Greek ξένος, host, as he utilizes the intermediate host of the parasite or some vicarious host for the cultivation of the parasite in question. He has applied the method to date mostly in cultivation of Chagas' trypanosome. A Brazilian leech was found convenient for the purpose; the trypanosomes taken up as it sucks blood multiply amazingly in the stomach. But for Chagas' disease, the true intermediary host is preferable. The bite of the bug in question, which is the host of Chagas' trypanosomes, is not painful, and consequently children do not object to let it be placed on them to bite and draw blood. It takes up from ten to five hundred times as much blood as could be examined with the microscope, and the bug, a large black insect with red markings, can then be set aside in a labeled tube and examined at leisure as the trypanosomes proliferate in its interior. Brumpt's communication is the leading article in the *Annaes Paulistas de Medicina*, 1914, iii, 97.

JOURNALS INDEXED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT JANUARY-JUNE, 1915

The following journals have been indexed in the Current Literature Department of THE JOURNAL during the past six months. Any of the foreign journals, except those starred, will be lent by THE JOURNAL to subscribers in the United States and to Fellows of the American Medical Association for a period not exceeding three days. Only one journal may be borrowed at a time. Requests for periodicals should be addressed to the Library of the American Medical Association and six cents in stamps should be enclosed. This covers the average expense of mailing a journal. Domestic journals can be obtained by sending the approximate amount direct to the respective publishers. Thus most of the journals indexed are accessible to the general practitioner, no matter where he may be located.

Albany Medical Annals. M. $2. 170 Washington Ave., Albany, N. Y.
American Journal of Anatomy. Bi-m. $5. 36th St. and Woodland Ave., Philadelphia.
American Journal of Diseases of Children. M. $3. American Medical Association, 535 N. Dearborn St., Chicago.
American Journal of Insanity. Q. $5. Johns Hopkins Press, Baltimore.
American Journal of the Medical Sciences. M. $5. Lea & Febiger, 706 Sansom St., Philadelphia.
American Journal of Obstetrics and Diseases of Women and Children. M. $5. Wood & Co., 51 Fifth Ave., New York.
American Journal of Orthopedic Surgery. Q. $3. P. Blakiston's Son & Co., 1012 Walnut St., Philadelphia.
American Journal of Physiology. M. $5. Johns Hopkins Medical School, Baltimore, Md.
American Journal of Public Health. M. $3. 755 Boylston St., Boston.
American Journal of Roentgenology. M. $5. 32 Adams Ave., West, Detroit.
American Journal of Tropical Diseases and Preventive Medicine. M. $2. P. O. Drawer 602, New Orleans, La.
Annales de gynécologie et d'obstétrique. M. 22 francs. Paris.
Annales de médicine. M. 23 francs. Paris.
Annals of Ophthalmology. Q. $4. Mermod-Jaccard Bldg., St. Louis.
*Annals of Otology, Rhinology and Laryngology. Q. $4. Mermod-Jaccard Bldg., St. Louis.
Annals of Surgery. M. $5. J. B. Lippincott Co., E. Washington Square, Philadelphia.
Annals of Tropical Medicine and Parasitology. Q. $5. Liverpool.
Archiv für Gynäkologie. Irregular. Price varies. Berlin.

EXPLANATION OF THE USE OF THE INDEX

This is an index not only to the reading matter in THE JOURNAL, but also to original articles in the principal medical periodicals of this and other countries. The reading matter appearing in THE JOURNAL is distinguished by the use of **black-faced numerals.**

The letters used to explain in which department the matter indexed appears are as follows: "E," Editorial; "C," Correspondence; "T," Therapeutics; "Ml," Medicolegal; "P," Propaganda for Reform; "ME," Medical Economics; "ab," abstract; the star (*) indicates an "Original Article" in THE JOURNAL.

This is a subject index and one should, therefore, look for the chief word, with the following exceptions: "Book Notices," "Deaths" and "Society Proceedings" are indexed under these titles at the end of the letters "B," "D" and "S." Matter pertaining to the Association is indexed under "American Medical Association."

All matter is indexed under the most important word of the heading used in THE JOURNAL, and also under the subject heading. For instance, abscess of the brain will be found under "abscess," as well as under "brain." Such titles as "ocular manifestations, etc." have been indexed under "Eye." Cross references have been liberally used.

The figures in parentheses refer to the paragraph, the number following to the page in THE JOURNAL.

ABDERHALDEN serodiagnosis, present status of, *1898

This reference is to an original article in THE JOURNAL, as shown both by the star and by the black-faced numerals indicating the page.

ACONITE in pneumonia, 1782

This reference, as indicated by the black-faced figures, is also in THE JOURNAL, and on turning to page 420 we find an answer to a question in the Department of Queries and Minor Notes.

ACID, uric, in blood, colorimetric determination of, (84) 1877

In this reference, the (84) indicates that the article is in the Current Literature Department and the fact that the page number is in black-faced type shows that the article is abstracted and discussed in THE JOURNAL. Turning to page 1877 we find (84) refers to an article by S. R. Benedict in the *Journal of Biological Chemistry,* April.

ABSCESS, brain, after blocking trigeminal nerve for removal of teeth, (97) 1690

The fact that in this last reference the page is given in ordinary type indicates that only the title of the article is given. Turning to page 1690 we find that the numeral (97) refers to a paper on that subject by F. Bannes which appeared in *Medizinische Klinik,* April 4.

In the AUTHOR'S INDEX are the names of the authors of articles which have appeared in THE JOURNAL of the American Medical Association and of articles that have been listed from week to week in the Department of Current Medical Literature as having appeared in other journals. The black-faced numerals indicate that the article is in THE JOURNAL, either in full or in abstract. The star (*) preceding the page number, indicates an original article.

SUBJECT INDEX

A

ABDERHALDEN, defensive ferments of, (54) 1942
  serodiagnosis and defective mental and physical states, 2014—ab
  serodiagnosis, basis of, (16) 780
  serodiagnosis, cancer, (165) 182
  serodiagnosis, digestion of liver tissue in, applied to alcoholics, (94) 948
  serodiagnosis, mechanism of, (62, 63) 1108
  serodiagnosis, *negative,* in injury of head with oncoming epilepsy, operation, drainage of cyst, (90) 1109
  serodiagnosis, nervous and mental diseases, (8) 937, (131) 1039
  serodiagnosis of diseases of liver, 81—ab
  serodiagnosis, pregnancy, cancer and nervous diseases, experience with, (41) 1451
  serodiagnosis, pregnancy, practical application, (153) 544
  serodiagnosis, present status of, *1898
  serodiagnosis, production of specific bacterial ferments as detected by, (66) 1358
  serodiagnosis, rationale of Wassermann reaction and, (20) 699
  serodiagnosis, results of clinical investigations based on, (36) 621
  serodiagnosis, specificity of, *735
  serodiagnosis, study of protective *ferments of blood by, after* transplantation of organs, (30) 1030
  serodiagnosis with normal and pathologic human serums, (77) 1360, (11) 2017
  serodiagnosis, year's work with, (13) 1029
ABDOMEN, acute, (57) 940
  acute diseases of thorax and, differential diagnosis between, (27) 1687
  acute, in children, (31) 1527
  acute pathologic perforations within, differential diagnosis between, (105) 1032
  acute surgical, (101) 1685
  acute surgical, in children, (87) 1615
  acute, tabes dorsalis simulating, (90) 1685
  adhesions, 2162—ab
  adhesions, electromagnet in prophylaxis of, (32) 279
ABDOMEN adhesions, injection of liquid petrolatum to prevent, (119) 705
  adhesions prevented with sodium citrate in hypertonic salt solution, (56) 371
  anesthetization of, (43) 1800
  angina of, (82) 188
  blue spot on, (138) 952
  care *of,* in infants and children, (101) 275
  chronic, 19 cases, (149) 180
  diagnosis with *reference to* pain, (137) 86
  disease and eye symptoms, (80) 1622
  disease, superior mesenteric vessels in, 1789—ab
  disturbances of, appendicitis as *factor* in, (147) 697, (134) 1194
  drainage, (8) 176
  foreign body in, Crossen's metnod of precluding possibility of leaving, (117) 778
  gunshot wounds of, (122) 180, (85) 625
  gunshot wounds of, compressive dressings in, (134) 1692
  gunshot wounds of, penetrating and perforating, 27 cases, (127) 1275
  hemorrhages, leukocytosis deceptive sign in, *1294
  incision, closing, improved method, (4) 1875, (120) 1879
  muscles, insufficiency of, in tuberculous, gastro-intestinal disturbances from, (60) 946
  muscles, segmental innervation of, (138) 627
  pain in, (76) 624, (70) 2099
  pain in upper, due to chronic disorders, (133) 1194
  pressure on, in artificial respiration, (78) 947
  Ptosis of: See Splanchnoptosis
  septic conditions of, *management* of, (84) 2019
  suction and circulation, (80) 1115
  Surgery: See also Laparotomies
  surgery, (140) 544, (144) 1362
  surgery, mortality of, analysis of, (44) 857
  trauma, accidental, immediate section in, (64) 1942
  tumor, inflammation, (106) 1281

ANAPHYLAXIS: See also Auto-Anaphylaxis; Immunity
ANAPHYLAXIS, (71) 371
  and immunity, (82) 84
  drug, (42) 1941
  effect of, on nitrogen metabolism in rabbits, (48) 90
  following administration of tetanus antitoxin, (149) 544
  intracutaneous injection and, (36) 1112
  pregnancy and, (101) 376
  studies in, (52) 1451
  symptoms of, produced by toxicity of trypsin, (16) 1455
  to common foods, 2164—ab
ANARTHRIA due to syphilis, *51
ANASTOMOSIS, arteriovenous, futility of, in impending gangrene of lower extremity, (118) 1361
  arteriovenous, of portal vein wards off necrosis of liver after ligation of hepatic artery, (104) 625
  arteriovenous, rationale of, *873
  axillary artery, end-to-end, (129) 1361
  intestine, lateral, new method, (122) 859
  lateral, of blood vessels and operation for arteriovenous aneurysm, (24) 1941
  lateral, of blood vessels, new method of, 365—ab
  uretero-enteric, (21) 1106
ANATOMY, applied, of arm, (50) 622
  illustrations in works on, before and during Vesalius' day, (72) 783
  in 17th century, *1373
  nomenclature, *1569
  of Vesalius and da Vinci, (74) 783
  revolution in, realized by Vesalius, (71) 783
  segmental, (76) 476
  vertebrate, comparative microscopic, (119) 1039
ANCYLOSTOMA not ankylostoma, 1081—E, 1346—C, 1519—C
ANEMIA, aplastic, experimental, of benzol poisoning, factors of coagula in, with reference to origin of prothrombin, (64) 1795
  aplastic hemolytic, in children, (77) 1037
  aplastic, paraplegia dolorosa terminated by, (79) 469
  aplastic, staphylococcus sepsis with, following gonorrhea, (78) 549
  blood-picture in, influence of infections on, (56) 375
  cause of, in Malay, Dr. S. T. Darling of Rockefeller foundation to study, 1855—E
  experimental pyrodin, ulcer of stomach and duodenum under, (143) 952
  hemolytic, iron retention in organs in, (38) 1035
  in children, (68) 91
  in Colorado, (63) 941
  in stomach cancer with bone marrow metastases, (19) 943
  infantilism and associated splenomegaly, case of, (155) 627
  iron and iron metabolism in, experimental work on, (126) 276
  Leishman: See also Kala-Azar; Leishmaniasis
  pernicious, (3) 271, (146) 552
  pernicious, blood transfusion in, 613—ab
  pernicious, in infants, (140) 952
  pernicious, in roentgenologist, (19) 780
  pernicious, neuropathologic findings in, with psychic implication, (67) 1032
  pernicious, primary, blood in, unusual condition of, 2162—ab
  pernicious, primary, factors of coagulation in, (12) 2017
  pernicious, salvarsan and neosalvarsan in, (11) 1195
  pernicious, splenectomy in, (94) 285, (104) 696, *796
  pernicious, treatment of, (79) 2106
ANEMIA, pernicious, with subacute combined degeneration of spinal cord, (2) 1797
  pseudoleukemic, of infants, in twins, (130) 1530
  roentgenotherapy in severe, (24) 780
  severe, with leg ulcer, 2162—ab
  splenectomy for englared spleen with, (15) 779
  splenic, (45) 1107, (92) 1274
  splenic, or primary splenomegaly, (38) 1196
  splenomegaly with, (81) 1199
ANESTHESIA chart, clock dials on, *242
  chloroform, (28) 177
  chloroform and ether, (81) 1943
  chloroform and ether by vapor method, apparatus for, *824
  chloroform and ether in general, *904
  effect of operation and, on kidney function, as shown by phenolsulphonephthalein test, (13) 1190
  ether insufflation, (110) 619
  ether, new method, *1754
  general, controller of tongue and palate during, *1757
  general, for eye operations, (5) 1530
  general, from intramuscular injection of ether, (104) 1623
  general, heart and respiratory failure during, causes, (92) 550
  general, in gynecology, (39) 374
  glycosuria following, influenced by diet, body temperature and purity of ether, (26) 272, 668—E
  in gynecology, (30) 89
  in labor, (6) 614
  inhalation, influence of, on acidity of blood, (14) 615
  local and general combined, in major surgery, (10) 1526
  local and spinal, in genito-urinary surgery, (14) 856
  local, cesarean sections, abdominal, performed under, (119) 858
  Local, Congress on, meeting of, 352
  local, in operations for hernia and lacerated perineum, (76) 371
  local, in skin grafting by Thiersch's method, (4) 1453
  local, prostatectomy under, (136) 1361
  local, thyroidectomy under, (102) 942
  local, tonsillectomy under, abscess following, (24) 857
  local, vagina operations under, (115) 551
  local vs. general in surgery, (79) 1199
  local, with reference to nerve-blocking, (111) 1274
  magnesium sulphate, nature of, (83) 948
  narcotic, (112) 1274
  nitrous oxid for, in hospitals, manufacture of, (109) 1194
  nitrous oxid gas, in obstetrics, *812, *813
  nitrous oxid, in obstetrics, (63) 1273, 2015—ab
  nitrous oxid-oxygen, (94) 85, (87) 858, (143) 1362
  nitrous oxid-oxygen anoci-association, (52) 1795
  nitrous oxid-oxygen, deaths, reports of wanted, 1019
  nitrous oxid-oxygen, in general surgery and obstetrics, (79) 179
  nitrous oxid-oxygen, in obstetrics, 1187—ab, (28) 1527
  nitrous oxid-oxygen, syncope and fatal asphyxia under, (112) 619
  novocain-suprarenin infiltration-conduction, in inguinal hernia, (72) 2019
  practical, (113) 372
  sacral, (42) 774
  scopolamin, in nose and throat operations, (71) 1876
  scopolamin-morphin as preliminary to local, (113) 85, (148) 1944
  scopolamin-morphin, in labor, (96, 118) 85, (2) 176, (87) 371, 459—C (26) 540, (76, 88, 93) 542, (57) 857, (49) 1031, (55) 1192, (13) 1272, (53) 1273, (29) 1527, (59) 1528, (91, 97) 1616, *1723, *1728, (92) 1796, (73) 1802, (1, 2) 1874
  scopolamin-morphin, in labor, are women compelling physicians to use, 1933—ab
  scopolamin-morphin, in labor, in home, (88) 618
  scopolamin-morphin, in labor, in moving pictures, 1251—E
  scopolamin-morphin, in labor, lecture and picture of, 2157—C

ANESTHESIA, scopolamin-narcophin, (120) 619
  shock and anoci-association, (127) 620
  spinal, (41) 1192, (113) 1274, (18) 1880, (74) 2105
  spinal and local, combined, (41) 774
  spinal, in gynecology, (40) 774, (103) 1032
  spinal, novocain in 43 suprapubic prostatectomies, (34) 2022
  spinal, stovain, (107) 778
  spinal, vaginal hysterectomy under, (72) 1108
  suggested, removal of sebaceous cyst under, (17) 698
ANESTHETICS, (62) 1795
  liver function as influenced by narcotics and, (60) 1108
  permeability of cell altered by, (62) 1365
  refusal to submit to, for examination, 173—Ml
  resuscitation for alarming conditions brought about by, (156) 276
  sequences and methods, selection of, (27) 177
ANESTHETISTS, American Association of, meeting, 1925
  Interstate Association of, meeting of, 1008
  training of, as surgical assistant, (136) 1944
ANESTHETIZATION of abdominal cavity, (43) 1800
ANEURYSM, aorta, early, (86) 84
  aorta, simulating spinal tumor, (134) 626
  aorta, with recurrent fever, (11) 615
  arteriovenous, (25) 1945
  arteriovenous, among soldiers, 1513
  arteriovenous, of carotid, with division of vagus, hypoglossal and sympathetic nerves by bullet, (18) 2100
  arteriovenous, of femoral vessels following bullet wound through left thigh, (24) 545
  arteriovenous, operation for, 365—ab, (24) 1941
  carotid artery, external, simulating tumor in tonsil region, (62) 548
  electric treatment of, improved, (128) 379
  groin, plastic operations, (129) 2028
  gunshot, end-to-end suture of common carotid after, (93) 285
  gunshot wound and, 679
  hematomas and, (58) 475, (118) 949
  inguinal, large, transperitoneal ligation of external iliac in, (35) 1684
  kidney hematuria, symptomless, from calculus, tumors, early tuberculosis and, (3) 2100
  maxillary artery, spontaneous subsidence of, (58) 548
  operative treatment of, (88) 1280
  popliteal, in girl, Matas' restorative operation, (4) 1033
  thoracic, hemiplegia complicating, (146) 86
  traumatic pseudo-aneurysm, (31) 700
  treatment of, (136) 952
  wounds in war cause of, (67) 863, (97) 948, (118) 2028
ANGINA, Ludwig's: See Ludwig's Angina
ANGINA of abdomen, (82) 188
  pectoris, (17) 1455, (27) 2171
  pectoris, high frequency currents in, (133) 1797
  Vincent's: See Vincent's Angina
ANGIOMA, injection of boiling water in, Wyeth method, 464—ab
  liver, cavernous, in infant 6 weeks old, (41) 1107
  of cerebellum, (57) 2098
  racemosa of pia with epileptoid convulsions of Jacksonian type, *1575
  spinal cord, extramedullary, (51) 1192

APPARATUS, artificial pneumothorax, (6) 620, (27) 1684, (101) 2027
  atomizer bracket, new, *1069
  baby pocket scale, (7) 367
  blood transfusion, and new method, *1315
  bone clamp, new, *1753
  brace for extension in wounds of long bones, (94) 92
  brace, metal, for extension in fracture of humerus, (19) 278
APPARATUS, breast pump, (4) 1682
  carbon dioxid tension in alveolar air, determination of, (76) 1279
  chloroform and ether, administration of, by vapor method, *824
  electric-heated water-jacketed infant incubator and bed, *1068
  electric heater for staining bacillus tuberculosis, *823
  electric, improvised, for locating bullets in tissues, (51) 1036
  electric treatment of wounded nerves, (50) 1036
  ether, administration by intratracheal insufflation, portable, positive pressure, *138
  ether administration, new method, *1754
  ether mask, improved, *823
  face shield for nose and throat work, (68) 618
  fluoroscope switch, *1580
  for ambulatory treatment of fracture of tibia, (80) 1615
  for assisting in application of dressings about hip, *240
  for extension of fractures in war, (114) 1691
  for fractured bones, *2132
  for holding solution bottles in operating rooms, *584
  for immobilization and adjustable extension of fractures, (30) 1618
  for inactivation of serum, *584
  for injection of salvarsanized serum, *1317
  for localization by Roentgen ray, (8) 1275
  for localizing foreign bodies, (68) 186
  for measuring dosage of Roentgen rays, (79) 187
  for mobilizing stiff joints, adjustable, (100) 1623
  for moistening air, 611
  for producing simultaneous suction and pressure for tonsil and adenoid operations, (100) 1796
  for recording differential counts, *584
  for securing traction of lower extremities, (126) 1530
  for study of hearing capacity, (107) 377
  for therapeutic exercises, (113) 551
  for writing with teeth after loss of arms, (57) 2024
  Frank's segment capsules, adaptation of, for clinical use in recording pulse records, *1305
  head-mirror and face protector, new combined, (120) 85
  infant specimen urinal, *1908
  intubation, and tubes for treatment of chronic stenosis of larynx, *1066
  iodin fumigator, (117) 1194
  measuring board for infants, (106) 1878
  mechanical devices for overcoming writer's cramp, (91) 92
  orthopedic universal, (33) 2102
  pessary and tampon holder, improved, *1067
  retaining clamp for two-piece transfusion tube, *1580
  shield for prostatic examinations, *1909
  sphygmomanometer findings controlled by, (115) 866
  sphygmomanometer, portable, (82) 284
  splint, aluminum skeleton, in compound fractures, (7) 2022
  splint, flexible metal, adaptable to any angle of knee or elbow, (55) 83
  splint for fractures about elbow joint, adjustable, *1755
  splint, lateral pressure, for fractured neck of femur, *239
  sterilizer for dressings, portable, (22) 372
  suction, *1910
  telephone probe, theory of, (14) 779, (22) 1945
  to measure amount of blood in living body, (77) 549
  tray for holding gall bladder calculus, (115) 1194
  tubes for intra-urethral medication, *1754
  urethral clamp for postoperative urine incontinence, (107) 1878
  vacuum tube of Keidel in blood-culture work, *822
  walking casts, (77) 1949
  walking, extension, for fracture of femur, (26) 699
APPENDECTOMY, diverticulum of cecum following, (160) 181
  technic for, (92) 1117

- APPENDICES EPIPLOICAE, strangulation in hernia of, (137) 2029
- APPENDICITIS, (134) 180, (79) 2099
  - acute, and acute appendicular obstruction, (7) 183
  - acute, and appendicular peritonitis, pathologic changes in, (7) 1449
  - acute, at Massachusetts General Hospital, (30) 1941
  - acute, cause of, and pulse examination, (33) 1881
  - acute, 100 operations, end results of, (86) 1685
  - abdominal affections and, (147) 697, (134) 1194
  - anticolon bacillus serum and vaccine in, (9) 544
  - bacteriology of, 1584—E
  - bacteriology of, and production of, by intravenous injection of streptococci and colon bacilli, (60) 1359
  - catharsis after operation for, (120) 942
  - cecal stasis due to, (11) 176
  - chronic, abdominal Roentgen ray before operation for, (25) 1684
  - chronic, and chronic indigestion, (120) 697
  - chronic, conditions that simulate, (20) 545
  - chronic, differential diagnosis of, (82) 91
  - chronic, pylorospasm and duodenal ulcer, *1845
  - chronic, reflex disturbances due to, (93) 179
  - chronic, study of, (88) 1360
  - diagnosis, (80) 549, (70) 623, (114) 866
  - differential diagnosis of typhoid, gastro-enteritis and, (126) 1194
  - differentiation, complications and local anesthesia, (55) 1036
  - effusion into intestine wall simulating, (131) 1944
  - etiology and experimental production of, 1524—ab
  - factors in, 1931—C
  - false, (37) 2172

BALSAM OF PERU, emulsion of, 459
  for gunshot wounds, (87) 284
BANANAS in dietetic treatment, (78) 476
  ripening and storage of sweet potatoes and, 1164—E
BANDAGE, injury from negligently cutting through, 1870—Ml
  material, substitutes for, 356
BAŇG'S micromethod of concentration of blood sugar in health and disease, (22) 938
  test for sugar in blood, advantages of, (79) 624
BANNERMAN'S Intravenous Solution refused recognition by Council, 70—P
BANTI'S DISEASE: See Anemia, Splenic
BARDE, DR., death of, 163
BARRY'S Freckeless, 1346—P
BASEDOW'S DISEASE: See Goiter, Exophthalmic
BASOPHIL granules in blood corpuscles as sign of lead poisoning, (101) 1280
BASSINI operation, modified, for inguinal hernia, (86) 188
BATH: See also Balneotherapy; Hydrotherapy
BATH, continuous flow, and high blood-pressure, (110) 1275
  continuous, for open ulcerations, (108) 626
  continuous, for phlegmons, (70) 186
  continuous warm, in psychoses, 1347—C
  for wounded soldiers, (7) 860
  Nauheim, administration of, in England, (39) 1687
  thermal, with weak heart, (98) 1690
  trains, 1436, 1437, (33) 2171
BATHING in Great Salt Lake, metabolic influences of, (10) 1189
BATTLE field impressions, first, (57) 91
  fields, sanitation of, 1777
  naval, casualties in action between Pegasus and Königsberg, (13) 1880
  naval, collapse after, (80) 284
  naval, North Sea action of January 24, (14) 1880
BEDBUG, alimentary tract of, (25) 1363
  development of bacillus pestis in, and power to convey infection, (21) 1034
  fertilization in, (17) 1363
BEDSIDE records, 930
BEEF tonsils, alcoholic extract of, superior antigen for Wassermann reaction, (110) 377
BEER, drinking, Franklin's views on, 1933—ab, 2085—C
  production and food supply, (74) 1457
BEES, ants and cockroaches, possibilities of distribution of infection by, 1662—E
  poison of, in chronic rheumatism in children, (54) 1535
BEHRING antitetanus serum, (74) 947
  Roumanian decoration for, 1925
BELGIAN field hospitals need aid, 841
  "Odyssey," 354

BELGIAN physicians, aid for, 62—E, 65, 258, 354, 448, 449, 523, 602, 675, 755, 842, 914—E, 921, 1009, 1087, 1172, 1257, 1338, 1436, 1511, 1595, 1670, 1776, 1860, 1926, 2000, 2079
  physicians and pharmacists fund, 162, 450
  students, scholarships for, 1347—C
BELGIUM, health service for, 678
  more aid for, 1436
  Red Cross units for, 1008
BELL'S phenomenon, pathology of, (38) 1795
BELLADONNA, tolerance to, *658
BELL-ANS, 264—P
BENCE-JONES protein, 669—E
BENZENE: See Benzol
BENZIDIN test, dry, for invisible blood, (34) 474
BENZIN, carbon tetrachlorid noninflammable substitute for, (92) 1037
  substitute for alcohol in tincture of iodin, (106) 866
BENZOATES and benzoic acid, *1072
BENZOL, action of, experimental research on, (74) 1690
  and roentgenotherapy in myelogenous leukemia, (80) 469
  derivatives of, *1070, *1155
  fumes, acute fatal poisoning from, (41) 1112
  in chronic lymphoid leukemia, (12) 1111
  in leukemia, *1734
  in leukemia and lymphosarcoma, (12) 1195
  in lymphatic leukemia, (34) 1614
  in splenomyelogenous leukemia, *505
  medicinal, 53
  poisoning, experimental aplastic anemia of, factors of coagulation in, with reference to origin of prothrombin, (64) 1795
BERGONIE-KELLOGG method, new application of ergotherapy by, in obesity and other chronic disorders, (96) 1796
BERIBERI and diet, 1668
  infantile, (70) 91
  prevention of, among Philippine scouts, by modifications in diet, *1215
  serum, action of, on frog's vessels, (126) 1039
BERLIN, death rate in, last year, 2174—ab
  letter, 163, 260, 356, 452, 524, 603, 678, 757, 844, 922, 1009, 1090, 1174, 1259, 1341, 1438, 1515, 1597, 1861, 1926, 2003, 2081
  Remedy Company, 847—P
BESREDKA'S tuberculin, serodiagnosis with, and tuberculosis among syphilitics as diagnosed by this test, (27) 272
BICEPS *flexor cubiti, rupture of*, 8 cases, (27) 1940
BIFIDA, cranial and spinal, (62) 1032
BILE, accumulation of, in peritoneal cavity after gunshot wound of liver, (54) 862
  and pancreatic ducts, new growths involving, (6) 271
  cholesterin in, conditions that favor precipitation of, (144) 952
  duct, calculus in, duodenotomy in, (34) 1030
  duct, cystic and common, perforation at juncture of, primary suture, (101) 2020
  duct, diseases of liver, pancreas and, recent progress in, (123) 551
  duct, helminths in, (60) 1883
  duct, operations on, butterfly retractor in, (121) 858
  duct, repair and reconstruction of, (6) 177
  feeding of, collected from biliary fistulas, in obstruction of common bile duct, *1900
  pigment derivatives in echinococcosis of liver, (105) 551
  pigment, production of, outside of liver, (118) 1460, (107) 1538, (107) 1624
  pigment, relation of, to hemoglobin, (10) 372
  pigment, *test for, in body fluids*, (118) 1460
  pleurisy from transpleural wound of liver, (66) 1948
  technic for cultivation of typhoid bacilli from blood, (70) 702
  thickening of, gallbladder calculus from, (121) 1460
  tract, operations on stomach and, liver in relation to, (50) 617
  tract, pathology of, from clinical standpoint, (138) 1202
BILLET, ALBERT, death of, 2003
BINET-SIMON intelligence tests for feebleminded children, (122) 1460
  intelligence tests in psychoses of senium, (107) 1032
BIOLOGY and social science, 1124—ab
BIRCH TAR, oil from, as substitute for Peruvian balsam in infection of soft parts, (102) 625
BIRTH fracture of femur, treatment and end results, (56) 1273
  legal record of, 140—ab
  rate, declining, in Mecklenburg-Schwerin, (32) 781
  rate, declining, struggle against, in France, 1597
  rate, influence of war on, 1259
  rate, lowest, on record in England, 1173
  registration, securing better, 1322—ab
BITTER tonics, action on gastric secretion, *15, 58—E
BLACKWATER FEVER, (21) 1945
  and quinin, (8) 1362
  in Formosa, (1) 942
  schedule for recording cases, (18) 372
BLADDER, access to, with hysterectomy for prolapse of uterus, safe method, (59) 475
  atony and prostate obstruction, obscure forms of, (22) 1106
  bullet in, extracted through urethra (44) 944
  calculus, crumbling of, spontaneous, 3 cases, (41) 700
  calculus evacuator, (97) 179
  calculus, organic framework of, (110) 1201
  cancer, 1790—ab
  cancer, radium in, (70) 857
  cysts in, (157) 380
  diverticulum of, (52) 940, (44) 1107
  diverticulum of, operation for, (114) 1460
  diverticulum of urinary, congenital, in infants and children, (126) 1943
  exstrophy of, total, operative treatment, (49) 1365
  foreign body in, *1495, (100) 1878
  foreign body removed from urinary, (175) 87
  function after labor and after *gynecologic operations, 2092—ab*
  in chronic gonorrhea, 100 cases, (125) 1530
  in tabes, study of, (107) 858
  infected abdominal pregnancy with extension of long bones into, (125) 1110
  irrigation of urethra and, outfit for, (99) 371
  irrigation, quinin solution for, *505
  irritability in women, (81) 858, (9) 1029
  irritation of, from retroflexion of uterus, (133) 551
  obstructions at outlet of urinary, (99) 1616
  porous plaster and toxic symptoms in kidneys, urethra and, (58) 1278
  resection of, clamps in, (80) 371, (123) 543
  retroperitoneal abscess perforating into, (108) 1281
  rupture of, (80) 1796, (121) 1879
  rupture of, spontaneous, (74) 375
  suppuration in fallopian tube perforating into, (45) 1197
  syphilis of, (148) 1694
  tumors, (34) 1527
  tumors, contradictory incontinence of urine with, (70) 947
  tumors, fulguration in, (94) 777, *1050
  tumors, high frequency treatment in, (58) 371
  tumors of urinary, (104) 85, *580
  tumors, thermo-coagulation for, 6 cases, (119) 1367
  ulcer in woman, rare type of, (41) 1795
BLASTOMYCOSIS, (16) 1940
  coccidioidal granuloma and, differential study of, (29) 1613
  superficial, (68) 1036
BLAUD'S pills, quality of, 1344—P
BLENNORRHEA, inclusion, trachoma bodies as etiologic factor in trachoma and, (13) 1940
BLEPHAROCHALASIS, 2 cases, (21) 82
BLEPHAROPLASTY to cover eyeball exposed 14 years, (134) 2021
BLIND, education of semiblind, (16) 183
BLIND soldiers, aid for, 161, 922, 1861
  soldiers, industrial education of, 1597
BLINDNESS: See also Ophthalmia Neonatorum
BLINDNESS, cases of, (79) 858
  color and color vision, tests for, (25) 372
  ethmoidal operation followed by, (61) 2019
  monocular, alternating, transient, ending in loss of vision, (12) 1940
  night, among soldiers, (67) 1458
  preventable, causes of, (127) 1453
  prevention of, from standpoint of trachoma, gonorrhea and syphilis, (77) 618
  snow, (103) 625
BLOOD, acidity of, influence of inhalation anesthesia on, (14) 615
  agglutinins in, in cholera, (19) 1363
  altitudes, moderate, and, 670—E
  amino-acid content of cerebrospinal fluid and, in syphilitic and nonsyphilitic individuals, *126
  amino-acid content of muscle and, influence of meat ingestion on, (80) 1876
  amount of, in living body, apparatus to measure, (77) 549
  antithrombin in, test for, (47) 1528
  autoinjection of, (83) 703, (30) 1112
  basophile granules in, after shrapnel wounds, (89) 864
  basophil granules in, as sign of lead poisoning, (101) 1280
  catalytic reactions of, (44) 467
  cellular elements of, in skin diseases, (58) 775
  changes after injection of typhoid bacilli in rabbits, (128) 1202
  changes after muscular activity and during training, (1) 855
  changes during epileptic seizure, (123) 94
  changes in aqueous humor and, *in methyl alcohol inhalation, (37) 1795*
  changes in, at high altitudes, (2) 1189
  changes in children of European descent in tropical Australia, (15) 372
  changes in tuberculosis, (98) 1194
  characters, variability and interdependence, (18) 1363
  cholesterin in, during pregnancy, (99) 865
  clinical examination of, newer methods, (4) 1526
  clotting in, from tuberculous lungs, inhibition of, (56) 782
  coagulation after hemorrhage, *1768—E*
  coagulation, factors in, (68) 283
  coagulation, technic for, and clinical importance of examination of conditions regarding, (90) 376
  coagulation time, effect of hemorrhage on, (6) 856
  constituents of, 596—E
  content of, and absorption of sugar, (150) 627
  corpuscles, red, in advanced lung tuberclosis, (133) 627
  corpuscles, red, in urine of normal persons, (75) 476
  corpuscles, red, nuclear particles in, following splenectomy, (21) 1612
  corpuscles, red, number of, and percentage of hemoglobin, effect of work on, (27) 1795
  corpuscles, red, of guinea pig, relationship to parasite of yellow fever, (30) 373
  corpuscles, red, preservation of living, in vitro, 2163—ab
  corpuscles, red, vital staining of, (150) 552, (157) 627
  Corpuscles, White: See Leukocytes
  count chamber, improved rulings for, (67) 375
  count, differential, apparatus for recording, *584
  count, improved technic, (60) 91, (98) 1274
  count in pellagra, (11) 538
  culture, suggestions as to, (104) 1274, (111) 1360
  culture work, vacuum tube of Keidel in, *822
  cyst, solitary, in kidney with hematuria, (144) 379
  cyst, subperiosteal, of orbit simulating osteosarcoma, (150) 1944
BLOOD, derivation of white from red corpuscles in, in frog's mesentery, (91) 1367
  diseases and blood, 2164—ab
  diseases, functional diagnosis of, (90) 625
  effect of heat on transforming and binding power of, (66) 1108
  epinephrin in, at birth, (63) 1883
  exercise and, 1501—E
  flow, portal and hepatic and outflow from liver, (25) 368
  forming cells in liver in congenital syphilis with reference to lymphocytes and plasma cells, (59) 375
  H ion concentration in, determining variations in, 2162—ab
  in chronic lead poisoning, (69) 1199
  in dementia praecox with periodical fluctuations, (161) 627
  in pernicious anemia, unusual condition of, 2162—ab
  in starvation, 1081—E
  infants', antibodies to cow's milk in, (105) 1460
  injection of, in hemorrhage, *332
  lymphocytosis in, as sign of constitutional disturbance in chronic gastro-intestinal disease, (82) 1622
  microscopic examination of, in differential diagnosis of typhoid, (38) 1277
  nitrogenous bodies in, of children, (29) 781
  non-protein nitrogen and urea in, and phenolsulphonephthalein excretion in infants and children, 2094—ab
  non-protein nitrogen, in, estimation of, (14) 2096
  non-protein nitrogen in, in experimental uranium nephritis and nitrogen metabolism, (30) 272
  non-protein nitrogenous compounds in, in nephritis, with reference to creatinin and uric acid, (46) 1358
  occult, dry benzidin test for, (34) 474
  occult, hematein color test for, (57) 945
  occult, in feces, improved test for, (36) 2102
  of cholera hogs, attenuation of virus in, to prepare vaccine, (89) 696
  oxygen and carbon dioxid in, in *uremia, (75) 1884*
  parasites collected in Nigeria, (5) 372
  parasites, method of transmitting, (65) 1358
  peripheral, of kala-azar patients, examination of, (20) 621
  physical-chemical processes in, diagnostic import, (63) 782
  picture after typhoid and cholera vaccination, (82) 1949
  picture and splenectomy, (34) 279
  picture, aplastic type, aleukemia with, (91) 1690
  picture in anemia, influence of infections on, (56) 375
  picture, neutrophil, of Arneth, in children living in tropical Queensland, changes in, (13) 372
  platelet and leukocyte count, proportional, (91) 625
  platelets, extract of, experiences with, (56) 1619
  platelets, extract of, in uncontrollable hemoptysis, (105) 704
  pressure, abnormal, correction of, (127) 276
  pressure and altitude, *1812
  pressure and diphtheria toxin, (64) 782

  pressure, high, intravenous injections in, dangers of, (73) 371

BLOOD pressure in children, estimation of, (11) 1686
  pressure in life insurance, (132) 1275, (57) 1795
  pressure in nephritis, (147) 552
  pressure in pneumonia, 1103—ab
  pressure in pregnancy, (67) 2099
  pressure in prognosis in severe obstetric hemorrhage, (16) 1532
  pressure in tuberculosis, (121) 372
  pressure, increased, (36) 1192
  pressure, present status of, (152) 276
  pressure readings in examinations for life insurance, (87) 941
  pressure variations, treatment, (102) 777
  production and lipoids, (120) 1202
  protective ferments of, study of, by Abderhalden method after transplantation of organs, (30) 1030
  ptosis test of physical fitness, 1990—E
  pumping forces outside of heart, (58) 1365
  residual nitrogen in, as test for kidney functioning, (66) 1536, (81) 1622
  serum, antitryptic power of, (129) 94
  serum, cholesterin content of, in inherited syphilis, (95) 1367
  serum, decanted, after severe hemorrhage and in hemophilia, 2 cases, (70) 1529
  serum, fresh human, arrest of hemorrhage in sepsis after injection of, (102) 704
  serum in alkaptonuria, 748—E
  serum, noncoagulable nitrogen coefficient of, in pregnancy and toxemias of pregnancy, significance of, (7) 1526
  serum, test of cerebrospinal fluid and, in syphilis of nervous system, (69) 857
  smears, staining method for, malaria parasites and, combined, *2131
  staining for lymph vessel tissues and, (56) 475
  staining of, vital, technic of, 929
  sucking insects in Central America, (130) 867
  sucking muscid larva, habits, life history and structure of, (57) 1615
  sucking power of Brazilian bug, (82) 1803
  sugar, clinical study of, (6) 2168
  sugar in, (122) 1039
  sugar in, Bang's test for, (79) 624, (22) 938
  sugar in, estimation of, simple accurate method, (75) 1452
  sugar in, guide in treatment of diabetes, (100) 1459
  sugar in, improved test for, (131) 1202
  sugar in, in children, (6) 367
  sugar in, in diabetes, (139) 1202
  sugar in, in eclampsia, (90) 1200
  sugar in, in health and disease, concentration of, by Bang's micromethod, (22) 938
  sugar in milk and, improved technic for test, (123) 1039
  sugar in, quantitative test for, *241
  sugar in, test of, (74) 695, (55) 782
  tetany from thickening of, (47) 547
  Transfusion: See Transfusion, Blood
  treponema pallidum in, in congenital syphilis at autopsy, (5) 773
  tubercle bacilli in, (42) 1113
  tubercle bacilli in, exceptionally, in chronic tuberculosis, (108) 1460
  tubercle bacilli in infants', (29) 1112
  tubercle bacilli in, test inocluation of guinea pigs for, (50) 1456
  typhoid bacilli found less frequently in, after vaccination, (81) 1949
  urea content of spinal fluid and, (77) 1876
  uric acid content of children's, (67) 2104
  uric acid content of, inhalation of carbon dioxid increases, (60) 475
  uric acid in, colorimetric determination of, (84) 1877
  uric acid in, how does it eixst, 2143—E
  vascular tone and distribution of, in surgical shock, (17) 1527
  vessel, anastomosis of, lateral, and operation for arteriovenous aneurysm, (24) 1941
  vessel, anastomosis of, lateral, new method, 365—ab
BLOOD vessel clamps of practical utility, (25) 615
  vessel conditions in orthopedic cases, importance of, (14) 1611
  vessel, congenital malformations of heart and, infectious origin of, (20) 780
  vessel, disease of small, as studied with ophthalmoscope, (22) 1684
  vessel disease, organic, gangrene without, (94) 179
  vessel, gunshot wounds of, (50) 862
  vessel, mesenteric, obstruction of, (99) 948
  vessel, mesenteric, thrombosis of, (119) 1282
  vessel, repair of, by free grafts of fatty tissue, *426
  vessel, submucous resection for obliterating, (44) 616
  vessel, suture of, injured in war, (19) 472
  vessel, velamentous, fetal death from rupture of, (20) 1798
  vessel, wounds of larger, (90) 549
  vessel, wounds of, remarkable effects of, (89) 1367
  viscosity of, and pulse in children, (15) 2170

  metastases or skeletal cancer, (39) 1614
  metastatic infections, acute surgical, of joints and, (113) 1032
  necrosis of, due to syphilis and tuberculosis, *211
  necrotic, as support, (42) 1535
  periosteal regeneration of, (100) 2020
  plate, Lane, dislocation of head of radius with fracture of ulna corrected by, (67) 1615
  plating, external, (64) 1615
  regeneration and repair, (103) 469
  repair, ununited fractures with study of, (6) 81
  sarcoma, ossification in, (3) 779
  semilunar, dislocation of, (125) 470
  semilunar, dislocation of, with fracture of cuneiform, (45) 700
  splint transplantation in recurrent spondylolisthesis with paralysis, *24
  stumps, changes in, after amputations, (42) 700
  supernumerary, of foot, Roentgen study of, (3) 692
  surgery, misapplied, (91) 1529
  surgery of joint and, modern, (104) 619
  syphilis, congenital, (28) 1875
  transplantation, (70) 1032, (32) 1191, (28) 1684
  transplantation (Albee method) for tuberculosis of spine, (8) 81, *400
  transplantation for tuberculous spondylitis, modified technic for, (67) 623
  transplantation in compound and comminuted fractures of tibia and fibula, (45) 1451
  trauma of, and tetany, (67) 946
  tuberculosis, (132) 1194
  tuberculosis of joints and, calcium in, (62) 475
  tuberculosis of joints and, etiology and pathology of, *17
  tuberculosis of joints and, heliotherapy of, at seashore, (103) 188
  tuberculosis of joints and, treatment, (62) 701
  tumor, giant cell, (126) 1361
  vitality and periosteum, (20) 368
  wounds of joints and, in war, (54) 1113
BOOKS, medical, use of, in refutation and cross-examination of expert witnesses, 1356—Ml
  scientific, improper use of, in cross-examination, 851—Ml
BORAX and boric acid, *1242
BOSTON Medical and Surgical Journal corrects untrue report of multiple births, 1589—E
BOTTLE, baby, new, (98) 1109
  poison containing, distinctive, 1161—ab
  solution, in operating rooms, device for holding, *584
BOWEL: See Intestine
BRACE, extension, for fractures, (77) 864
  extension, for long bones in war wounds, (94) 92
BRACHIAL artery, embolus of, arteriotomy for, (146) 952
  plexus, bilateral fibrosarcomatous degeneration of, in steer, (126) 867
  plexus, blocking of, 110 cases, (61) 549
  plexus, osteoplastic exposure of, below clavicle, (38) 1456
  plexus, reuniting, (53) 1031
BRADY, JAMES BUCHANAN, Urologic Institute, (52) 1876
BRAIN: See also Cerebellum; Cerebrum; Dura Mater; Hypophysis Cerebri; Pineal Gland; Skull
BRAIN abscess, (65) 695, (41) 1273
  abscess after blocking trigeminal nerve for removal of teeth, (97) 1690
  abscess, double frontal, 463—ab
  abscess, drain for, (114) 950
  abscess in paratyphoid, (24) 1880
  abscess, ocular symptoms of sinus thrombosis of otitic origin and, (21) 857
  abscess of frontal lobe, secondary to purulent frontal sinusitis, (108) 1616
  abscess of otitic origin, (25) 540, (106) 1943
  amputation of important portion of, 1437
  autonomic reciprocal activities of viscera and, *321
BRAIN, cavity formation within medulla oblongata, *988
  changes in cortex of, with general paralysis, (152) 627
  concussion of, treatment of, (72) 1949
  cortex, lesions and anomalies of, in dementia praecox, topographic distribution of, (10) 937
  cranial aspect of, and inner surface of cranium, (14) 943
  cyst of cerebellopontine angle of, operation for, (90) 179
  cystic tumors of frontal lobes of, 4 cases, (137) 379
  decompression operations in disorders of, value of, (122) 1194
  decompression operations on, osteoplastic resection of skull in, (22) 545
  drainage of lateral ventricle of, in cerebrospinal meningitis, (51) 1031
  edema of, (70) 371
  explorer, improved form of, *2130
  growth of, in young children, effect of nutrition and diseases on, (78) 284
  gunshot wounds, meningitis from extension to ventricles of suppuration following, (114) 2027
  gunshot wounds of spinal cord and, (101) 949
  hemorrhage, (131) 1275
  hemorrhage, lung complications of, (74) 1274
  hemorrhage, ventricular, 1936—ab
  in primitive man, (28) 1451
  injury to, continuous sleep for 3½ years after, recovery, (77) 91
  normal looking, in psychopathic subjects, (58) 274, (41) 616
  physiology of, (66) 1689
  postnatal growth of, under experimental conditions, 1935—ab
  preservation of, improved technic for, (94) 1538
  prolapse of, flap-door incision and drainage to prevent, (116) 2027
  prolapse of tissue, treatment of, (89) 625
  removal of right frontal lobe, in boy of 14 without apparent change in mind or character, (110) 286
  sarcoma of meninges of, round cell, (98) 1796
  sarcomatosis of spinal cord and, (164) 87
  sclerosis of spinal cord and, eye symptoms in, (105) 1118
  transplant of tissue of rabbit, histologic changes in, (89) 1537
  tumor, (93) 1878
  tumor, continuous clonic spasm of left arm due to, (13) 938
  tumor of third ventricle, *1903
  tumor, pathology of, (2) 1939
  tumor, results of operations for, *189
  tumor, treatment of, (3) 1939
  tumor, trigeminal disturbances from, aid in localization, (150) 2029
  vascular lesions in optic nerves and, changes in visual fields result of, *1549
  wounds of, psychic deficiency after, symptoms of, (64) 1802
  wounds of spinal cord and, in war, (63) 1278
BRAZILIAN nematelminth worms, (108) 1952
BREAD making in Hungary, restrictions as to, 1257
  making in Italy, restrictions as to, 1257
  partial removal of restrictions to, 1926
  properties of, (77) 2025, (35) 2102
  rice flour in manufacture of, 1777, (49) 2024
  rye must be mixed with wheat flour in baking, in Germany, 66
  war, digestibility of, (75) 1366, (69) 1689, (80) 1690
BREAST cancer, (150) 276, (127) 471, *707, (40) 1946
  cancer, aberrant tissue, primary, (141) 2029
  cancer and pregnancy, relations between, (42) 1197
  cancer, gelatinous, diagnostic sign of, *1653
  cancer in man with healed miliary tuberculosis, (56) 617
  cancer of uterus and, actinotherapy for, (97) 2027
  cancer of uterus and, radiotherapy and intravenous chemotherapy in, (99) 2027
  cancer, recurrent, limits of operability of, *1749

- BREAST cancer, traumatic, legally established case of, (17) 88
  - chloroma, myeloid, of, (40) 1364
  - diseases of, treatment, (68) 371
  - funnel, treatment of, (143) 86

  feeding, whey in, (4) 773
  fever in newborn, transitory pathology and treatment, (28) 473
  food intoxication in, metabolic disturbances of intestinal tract with reference to, (81) 1796
  foods, proprietary, nutritive value of, (6) 1272
  foundling home for, problems of, (10) 1874
  fractured bones in children and, *fixation of*, (22) 1527
  gastro-intestinal diseases in, disturbance of circulation in acute, (26) 473
  gastro-intestinal glands in, functional insufficiency of, severe, (133) 1040
  gastro-intestinal hemorrhage fatal in newborn, (42) 1946
  growth in, prenatal and postnatal, (13) 1526
  health contest educational factor in preventive medicine, (153) 698
  heart disease in, congenital, 2167—ab
  hematoma of lower eyelid in, symptom of infantile scurvy, (3) 1195
  hemiplegia, *1577
  hemiplegia affecting left half of body. (2) 1944
  hemorrhagic disease in new-born, (103) 619
  hemorrhoidal nodules in newly born, (56) 281
  hospitals and hospitalism, 265—C
  hospitals for, are they necessary, *1
  hunger in, after feeding, onset of, *1822
  hydrochloric acid in stomach contents *of*, (97) 1367
  hygiene and medical care, (53) 622
  imbecility in, with transient apraxia of one hand, two cases, *(86) 703*
  in Chicago Municipal Tuberculosis Sanitarium, provision for, 72—C
  inanition in habitual luxation of lower jaw in, (76) 284
  incubator, care and feeding of, (126) 858
  institutional care of, outside of institutions, 79—ab
  intestines of, flora in, (105) 1691
  intestines, permeability of, for casein of cow's milk, (67) 476
  intussusception in, danger of delay in diagnosis and treatment of, (99) 696
  jaundice in newborn, (109) 1194
  jaundice in newborn, an infectious disease, (99) 1201
  jaundice in newborn, cause of spastic cerebral diplegia, (9) 1105
  jaundice in newborn, etiology of, (105) 1201
  keratomalacia in, fed on buttermilk, (105) 1804
  kidney function test in older children and, (108) 93
INFANT, Lange colloidal gold reaction in cerebrospinal fluid of children and, (2) 367
  leukemia, myelogenous, in 9 months old, 2167—ab
  leukocyte counts during digestion of bottle fed (2) 1682
  liquid paraffin in, (24) 1191
  liver abscess in 5 weeks old, (3) 1685
  malnutrition in, dietetic treatment of, (107) 1274
  measles and immunity, (103) 1623
  measuring board for, (106) 1878
  meningitis, epidemic cerebrospinal, eight cases, (6) 2022
  meningitis in newborn, 2166—ab
  metabolism and nutrition, studies on (7) 1272
  milk, pure, importance of, (2) 81
  mineral metabolism in, on breast milk and albumin milk, (88) 2026
  mortality, density of population and, 1753—ab
  mortality due to labor, *2048
  mortality in New York State, 1574—ab
  mortality in so-called foundling institutions, 79—ab
  mortality index of social welfare, 410—ab
  mortality, means to reduce, (85) 2025
  mortality of newborn, institutional, *287
  mortality, reduction of, (114) 180, (118) 1797
  mortality, university extension work for prevention of, 79—ab
  nasopharyngitis cause of protracted fever in, (102) 1538
  new-born, should it receive anything during first two or three days, (95) 371
  nonprotein nitrogen and urea of blood and phenolsulphonephthalein excretion of children and, 2094—ab
  nose sinuses in, disease of, (51) 1113
  nursing, *502
  nutrition disturbances of, (23) 368
  nutritive diseases of, (6) 277
  otitis, acute, (51) 774
  otitis media, suppurative acute, treatment of, (117) 1797
  parotitis in, primary suppurative, unilateral, three cases, (135) 867
  pemphigus foliaceus of new-born, 81, 542
  premature, (139) 1194
  pyelitis cause of obscure fever in, (35) 1613
  pylorus stenosis in, (29) 82, (98) 1616, (60) 1948
  pylorus stenosis in, operated on by Keefe method, (7) 176
  record charts for newborn, (16) 540
  respiration incubator for energy metabolism of, (4) 367
  salt fever and sugar fever in, from contamination of water, (25) 1617
  scleroderma in new-born, (92) 1690
  scorbutus in, (50) 1947
  spasmophilic dyspepsia in, (70) 91
  stomach content of, acidity in, (85) 92
  strabismus in, importance of early treatment of, (75) 84
  syphilis, congenital, without Wassermann reaction, (83) 1690
  taenia saginata with structural abnormalities and spurious parasitism in, *1972
  tubercle bacilli in blood of, (29) 1112
  tuberculin reaction in breast-fed, after diagnostic dose to mother, *1312
  tuberculosis bacillemia in, primary, (16) 2170
  tuberculosis in new-born, (8) 1272
  tuberculosis in, provision for, 360—C
  tuberculosis, lung, with cavities, (57) 862
  typhoid in children and, high caloric diet in, (5) 1682
  underfed, (55) 1456
  ureter in new-born, (71) 946
  urine excreted by, measurement of, (59) 91
  venesection and intravenous injections in, technic for, (108) 286

INFANT, vomiting of, uncontrollable, sweetened condensed milk for, (101) 285
  weight, drop in, with rise in temperature in new-born, (26) 1532
  weight, postnasal loss of, and compensatory overgrowth following, (16) 1526
  welfare campaign, results of, 25—ab
  welfare, German association for, meeting of, 1438
  welfare, provisions for, during war, (46) 1197
INFANTILISM, anemia and associated splenomegaly, case of, (155) 627
  kidney, (22) 1191
  pancreatic, (17) 2022
INFECTION, acute, heart in, (129) 276
  acute, in animals, protective value of aqueous extract, Hiss, of leukocytes, (81) 696
  acute, lymphatic leukemia in, after removal of spleen, (43) 616
  acute, suppurative, vaccine therapy in, present status of, (98) 275
  acute surgical, treatment of, (83) 1615
  acute, treatment of, (115) 858
  ants, bees and cockroaches as possible distributors of, 1662—E
  bacterial, *1814
  camphor and phenol in, (120) 93
  chronic, and neuroses, (73) 2099
  chronic, and recovery without immunity, physical basis of, (15) 1105
  dahlia in, (3) 1793
  focal, and bacteriology of arthritis, (54) 468
  focal, and systemic diseases, (168) 182
  focal chronic, of nose, throat and ear, cause of general infection, (109) 1943
  focal experimental, and clinical medicine, (69) 1274
  focal, functional liver failure from, persistent glycosuria symptom of, (152) 544
  focal, of teeth cause of eye involvement, two cases, (74) 1685
  in operations, aseptic technic, *1369
  in surgery due to lack of boiling of instruments, *1313
  influence of, on blood picture in anemia, (56) 375
  joints, phenol injection in, (12) 693
  latent, affecting surgical measures, (71) 1037
  local, due to intravascular dissemination of bacteria, (119) 1361
  mouth, responsibility of physicians in, (66) 2019
  oil from birch tar as substitute for Peruvian balsam in, (102) 625
  Puerperal: See Puerperal Infection
  rheumatism, endocarditis, arthritis deformans, ulcer of stomach and cholecystitis due to, (50) 774
  septic, perforation of esophagus followed by, (71) 2099
  septic, resistance of thorax to, (87) 864
  stasis and edema, (39) 1534
  systemic, mouth as source of, (70) 1274
  systemic, tonsils and, (39) 1192
  systemic, tonsils and adenoids and, (55) 178
  teeth as foci of, (82) 1193
  tonsils, (3, 7) 2169
  tubercle bacilli, human and bovine type, simultaneous in, in child, (33) 2097
  urinary tract, chronic, in women, laboratory diagnosis of, 2092—ab
  vaccine therapy of, (58) 1192
  wound, and trauma, (51) 1882
INFECTIOUS DISEASES, acute, Ehrlich's differential reaction in urine in, (53) 1113
  acute, myocardial changes following, (86) 618
  acute, strychnin and caffein as cardiovascular stimulants in, (19) 1191
  air-borne, and weather, (24) 88
  an unnecessary waste, 890—ab
  autogenous serotherapy in, (93) 1280
  cellular factor in, *649
  colon bacillus vaccine in, (50) 782
INFECTIOUS DISEASES, common, 54—T
  ferment activity of blood serum in, (44) 2097
  in army, prophylaxis of, 355
  in South America, recent investigations, (44) 695
  Japanese Institute for, 353
  malignant syndrome in, (36) 1364, (21) 1617
  notifiable, at Vienna, 1901-1910, (106) 93
  specific serum of convalescents in, 1915—E
  specific skin tests in, new uses of, (11) 938

  in *marginal placenta praevia*, (131) 469
  in rheumatic arthritis, (11) 692
  in uterus hemorrhage, (102) 696
  standardization, 1249—E
  therapeutic value of, (3) 277, (47) 371
PITUITRIN, action of, on acute heart failure and incompensate heart lesions, (39) 273
  in obstetrics, (178) 87, (3) 1874
  injections of, and milk secretion, (9) 856
PLACENTA, adherent, management of placental stage of labor with reference to, 2015—ab
  diagnosis of one or more, at birth of twins, (89) 1200
  expulsion of, to facilitate, 2062
  extract, active substance isolated from ovary and, (61) 1114
  extract, production of abortion and labor with, experiments in, (131) 1110
  full-term, nine-millimeter human embryo in margin of, (104) 2020
  praevia, abdominal cesarean section following interposition operation for uterus prolapse complicated by, (88) 1032
  praevia, advantages of external version, (25) 1533
  praevia, fetal heart sounds in, study of, (7) 1029
  praevia, pituitary extract in marginal, (131) 469
  praevia, treatment of, (101) 1201, (3) 1526, (125) 2021
PLACENTA, premature separation of, and eclampsia, (41) 2023
  proteins in skin reactions of human body, specificity of, (3) 176
  retention of, after abortion, (49) 2103
  retention of, and puerperal infection, (71) 283, (63) 1114
  retention of scraps of, (105) 377
  velamentous, fetal death from rupture of, (20) 1798
PLAGUE, bubonic, (98) 284
  bubonic, infection, modified in rats and guinea-pigs, (114) 697
  bubonic, laboratory diagnosis of, (21) 1029
  campaign against, in New Orleans, 257, (121) 778, 1256
  declining in Dutch East Indies, 2080
  distribution of, and climate, 1162—E
  epidemiologic observations in Madras Presidency, (11) 1033
  immunization by living avirulent cultures (Strong), (14) 1033
  immunization by pseudotubercle bacillus, (13) 1033
  in Denmark about 1600, (148) 380
  in Havana, *29, 1435
  in Italy, prophylaxis of, 65
  in Stockholm about 17th century, (146) 627
  infectivity in, persistence of, (19) 1034, 1251—E
  influence of race on efficiency of antigen, (15) 1034
  pneumonic, prophylaxis, of, (82) 624
  pneumonic, views regarding, 59—E
  rat, facts about, 1079—E
  rats, finding fleas on, 126—ab
  transmission of, by fleas, mechanism of, (20) 1034
  vaccination against, body-strain of, (12) 1033, (16) 1034
  vaccination against pneumonia and, (25) 2022
  vaccine, ultraviolet light as germicide in preparation of, (18) 1034
PLANTS, disease resistance in, 2141—E
  stinging hairs of, 267—ab
PLASMA cultures, connective tissue changes in, (62) 863
  removal, 514—E
PLASMAPHAERESIS, 514—E, 2163—ab
PLASTER, adhesive, double coated, in radium and roentgenotherapy, (83) 275
  adhesive, dressings with, for war wounds, (47) 1801
  casts, adjustable, extension, (39) 2102
  casts and dressings, technic for, (53) 475
  casts, bridge, (37) 1800
  casts, bridge, for fractures in war, (53) 1801
  casts, dangers of, (66) 1278
  casts, fenestrated, (100) 704
  casts, fenestrated, technic for making, (76) 1037
  casts for fracture of femur, technic for, (88) 284
  casts, forcible traction of leg while applying, (13) 1611
  casts, improved extension, (83) 2025
PLATINUM wire, nichrome as substitute for, in bacteriologic inoculators, *1069
PLAUT-VINCENT'S ANGINA: See Vincent's Angina
PLETHYSMOGRAPHIC examinations of normal and sick children, (116) 93
PLEURA, damage of endothelium of, at operations and with artificial pneumothorax, (60) 549
  echinococcosis of lungs and, (96) 1117
  effusion in children, radiology of, (74) 187
  effusion with artificial pneumothorax, (127) 778, (118) 866
PLEURISY, abdominal symptoms in pneumonia and, (116) 1194
  bile, from transpleural wound of liver, (66) 1948
  dry, artificial pneumothorax in, (7) 1530
  dry, pleurisy with effusion and empyema, interrelationship of, (88) 84
  in syphilitics, (104) 1460
  pneumonia preceded by, with jaundice following, (26) 1358

PLEURISY, purulent, artificial pneumothorax complicated by, (42) 1618, (56) 1947
  purulent, treatment, (120) 626
PLURIGLANDULAR insufficiency, incidence and treatment, (34) 546
PNEUMATIC tools, Raynaud's disease in stonecutters using, *582
PNEUMATOCELE, intracranial, following gunshot wound, two cases, (115) 2027
PNEUMOCOCCUS, biologic classification of and serotherapy of lobar pneumonia, (87) 1685
  in tuberculous sputum, types of, (64) 775
  infection and immunity, (89) 275, (93) 371, (4) 1195
  infection, autogenous vaccines in, (15) 1531
  infection, extensive destruction of vulva due to, *1239
  peritonitis, (149) 86
  peritonitis during puerperium, (107) 949
  [illegible] to, and

  infected, open treatment of, *1829
  infected, salt solution and healing of, 1765—E
  infected, treatment of, (4) 1616, (14) 1617, (10) 1686, (24) 1687, (9) 1944, (18) 1945
WOUNDS, infection of blood by anaerobic organism secondary to, (16) 1617
  intestine, (72) 1115
  intestine, treatment of, in war, (48) 1800
  jaws, (29, 48) 474, (54) 782, (91) 948
  jaws, prothesis after, early and adequate, (79) 1457
  joints, after-treatment, especially of shoulder, (120) 551
  joints and bones in war, (54) 1113
  light and air aids in healing suppurating, (87) 549, (95) 550
  light in, intensive artificial, (57) 1114
  liquid paraffin in, in war, (69) 1801
  liver, transpleural, bile pleurisy from, (66) 1948
  lungs, (66) 623, (55) 1113, (37) 1456
  lungs, experiences with, (43) 1113
  lungs, tardy pneumothorax after, (73) 1457
  median nerve, pain after, (27) 1456
  methyl violet in local treatment of, (93) 1623
  military physician with ninety-seven, 677
  modern projectiles, (148) 2029
  nerve concussion due to bullet and shell, (5) 544
  nerves, curve of reaction of degeneration in estimation of injury and prognosis in, (34) 1800
  nerves, electric treatment of, improvised apparatus for, (50) 1036
  nerves, in war, (47) 474, (37) 862, (48) 945, (46) 1277, (52) 1365, (33) 1618
  nerves, in war, calf's artery as protecting sheath, (85) 1199
  nerves, in war, electric tests and vital staining in examining, (50) 1197
  nerves, treatment of, (27) 1112, (70) 1115, (52) 1198
  nervous system, (95) 92, (66) 549
  nervous system, tardy effects of, (91) 1950
  nose, sinuses, throat and larynx, in war, (43) 1881
  oiled silk for burns and, (25) 1456
  operative, open, iodin treatment in, (107) 1460
  orbit, operative treatment, indications for, (27) 699
  osteomyelitis of spine after, (45) 1882
  oxygen, subcutaneous injections of, dosage and technic, (54) 2024
  pelvis, extension in treatment of, (112) 1201
  peripheral nerves, in war, (64) 1278, (68) 1366, (61) 1456, (68) 1689, (89) 2026, (43) 2103, (20) 2171
  peripheral nerves, in war, early operative treatment, (33) 474, (46) 1800, (78) 2025
  peripheral nerves, treatment, (28) 2101
  polyvalent serum for, direct application of, (36) 1277
  potassium permanganate in tetanus-infected and sloughing, (20) 372
  produced by German artillery projectiles, phosphorus in, 1089
  received in battle, *1224
  roentgenotherapy of, (56) 91
  salicylic acid in, (7) 1033
  salt solutions in treatment of, 912—E, 1765—E, 2152
  septic, embalmment of, (23) 861
  septic, injection of fresh human blood serum to arrest hemorrhages in, (102) 704
  septic, prevention and treatment of, (6) 87, (8) 2169
  serotherapy of, (25) 2101
  shell, in present war, experiences of, (7) 471
  shell, indirect, (40) 90
  shell, left shoulder, (39) 2022
  shrapnel, basophile granules in blood after, (89) 864
  skull, (57) 475, (91) 549, (118) 551, (84) 1690, (113) 2028
  skull, grazing, (71) 1199, (62) 2104
  skull, grazing, operative treatment of, (64) 2025
  skull, tangent, (90) 948
  skull, treatment of, 1862
  soft parts, treatment of, (63) 1536
  soil-contaminated, principles in treatment, (27) 1196
  spinal cord, early cystostomy in, advantages of, (102) 1038

WOUNDS, spinal cord, in war, (88) 948, (101, 105) 1039, (123) 2028, (37) 2102
  spinal cord, in war, laminectomy for, (38) 1533
  spinal cord, in war, retention of urine with, treatment of, (115) 1691
  spinal cord, lower end, (107) 1039
  spinal cord, operative treatment of, (84) 624
  spine, by shrapnel, low temperature with, (12) 860
  stab, of heart and lung, (95) 1117
  stab, of pregnant uterus, (142) 379
  statistics of, received in war, 355
  stay stitch for deep, *1317, 1781—C
  sterilization of, (103) 550
  suppurating, open treatment of, (83) 1457
  thermal mineral waters, beneficial action of, (72) 1366
  thigh, treatment of, (51) 782
  thorax, in soldiers, 1512
  thorax, treatment of, 1862
  treatment, 162, (87) 625, (12) 1880
  treatment by Danysz method, 1341
  treatment by very dilute antiseptic solutions, 677
WOUNDS, treatment of, common errors in, (63) 375
  treatment of, in war, (13) 277, (15) 278, 756, (86) 1116, (22) 1196, (62) 1801, (27) 1945
  treatment of open, (52) 1882
  treatment, on battle-field, (74) 91
  trioxymethylene gauze for, (26) 89
  ultraviolet rays in after-treatment of, (45) 1456
  ultraviolet rays in suppurating, (72) 1279
  urinary tract, (103) 1038
  vaccine therapy for suppurating, (32) 621
  varnish in dressing of, (58) 700, (104) 866
  venereal disease and course of, (58) 2024
  war, 3 months' experience with, (36) 374
WRIST, accidents with overstretching of elbow and, (47) 700
  Madelung's deformity of, (35) 1527
  semilunar bone of, luxation of, 3 cases, (57) 1198
  trauma of, disturbance in growth and deformity 10 years after, (93) 625
WRITERS' cramp and wryneck, massage in, (17) 1357
  cramp, mechanical devices for overcoming, (91) 92
WRITING with teeth after loss of arms, device for, (57) 2024

  parasite of, and erythrocytes of guinea pigs, (30) 373
  pathology of, in guinea-pigs, (30) 1034

Z

ZINC sulphate, *2065
ZOOPARASITE, rare, in man, 1769—E
ZORAB operation for glaucoma, (101) 1529

AUTHOR INDEX

In this Index, as in the Subject Index, the black-face type refers to reading-matter in The Journal; the light-face to articles in other journals and not abstracted in the Current Medical Literature Department. The asterisk (*) preceding the page reference indicates that the original article appeared in The Journal. The numbers in parentheses indicate the numbered paragraphs on the pages referred to. The numbers not in parentheses indicate pages.
